IN CARDIAC STRAIN OF
HYPERTENSION

DIURBITAL^{*} (GRANT)

VASODILATOR • SEDATIVE • DIURETIC

Hypertrophied heart associated
with long-standing hypertension
also showing myocardial
scarring

By slowly but effectively reducing blood pressure, DIURBITAL tends to act as a prophylactic against cardiac hypertrophy, myocardial fibrosis, and other serious heart impairments which may follow long standing hypertension

The combination therapy of DIURBITAL vasodilatation, sedation and diuresis, is accomplished through the utilization of three time tested ingredients THEOBROMINE SODIUM SALICYLATE 3 grs, Phenobarbital $\frac{1}{4}$ gr, and Calcium Lactate $1\frac{1}{2}$ grs

DIURBITAL has clinically demonstrated itself of value in treatment of hypertension and associated conditions, angina pectoris, myocarditis, arteriosclerosis with edema counteracting coronary spasm, etc

Enteric coated DIURBITAL (to prevent gastric irritation or upset) generally affords prompt symptomatic relief of the distresses of dizziness, headache, apprehension, insomnia and nervousness

Available in bottles of 25 and 100 tablets at all pharmacies
Suggested dosage 2 tablets, three times daily

Editorial

Acc No. 3602
Cl No

Take It Away, Asclepius Acc 8.12.61

Most potent, grave, and reverend signors, my very noble and approved good masters, fellow physicians of the Medical Society of the State of New York, greetings In this year, 1941, in obedience to the mandate of your late House of Delegates, in a resolution introduced by the New York County delegation, your Voice ascending high over the radio will be heard in the land

In days gone by, medicine followed the advice of Horatio to Hamlet "Be thou familiar, but by no means vulgar Beware of entrance to a quarrel, but being in, give every man thy ear, but few thy voice take each man's censure, but reserve thy judgment" So look you, gentle Sirs, if quarrel there be, how it is not of our seeking, we "don't complain of Betsy or any of her acts, exceptin' when we've quarreled and told each other facts" Medicine has listened these many years Now it must speak

But with what voice? The "big manly voice, turning again toward childish treble" piping and whistling in his sound? A "distant voice in the darkness"? The voice that "sounds like a prophet's word",

and in its hollow tones are heard "The thanks of millions yet to be"? Shall it be "a monstrous little voice"? Or will we "roar you as gently as any sucking dove, we will roar you, an't were any nightingale"? For look you, Sirs, you cannot speak without a voice, be you men or angels

What then is to be done? How grapple with this problem of "microphonetics"? The tongue of medicine has always been the pen of a ready writer Now that medicine in person must step up to the microphone in its own and in the public interest it can ill afford to speak with "The watch dog's voice that bayed the whispering wind," and yet in all the days of our years no one has taught us how to speak And speak we must Plainly, without affectation, simply, but without monotony, agreeably, as one who would persuade In short, medicine must now add to its curriculum the study of comprehensible speech, the art of good English diction The JOURNAL suggests that plans for such study and practice might well be formulated for the coming year by the Council Committee on Publicity

Third Annual Congress on Industrial Health

Arrangements have been completed for the third Annual Congress on Industrial Health, sponsored by the American Medical Association, to be held Monday

and Tuesday, January 13 and 14, 1941, at the Palmer House in Chicago

These meetings are open to all physicians and others interested in the indus-

trial health movement There is no registration fee

Industrial health is of the utmost importance to the Nation at all times, but more especially at this time when national preparedness depends so greatly on industrial production Designed to acquaint the physician and others with the rapidly expanding importance of preventive medicine and surgery, this congress should be of vital concern to all those interested in the welfare of industrial organization

"Since every man-hour of production is vital at this time, the program of the congress is intended to be as helpful as possible to physicians called on to control those factors which in the past have contributed greatly to the incidence and costs of industrial absenteeism In the field of trauma the hand and the eye have proved to be particularly vulnerable Symposiums have therefore been developed to present the best current opinion on the management of these costly forms of industrial disability Of the occupational diseases, dermatitis has long been recognized as the most troublesome A series of demonstrations has been planned to include discussion of the criteria for diagnosis of industrial cutaneous disorders as well as accepted methods for the treatment and placement of susceptible employees Among non-occupational diseases the common cold and influenza annually exact an enormous toll through loss of earning capacity and disruption of production schedules "

The question of the availability of trained personnel in industrial health is a serious one The character of the work is intermediate between private practice and public health It requires knowledge of the engineering problems and of the processes involved in the par-

ticular industry in which the worker is employed

"This problem also will be discussed from the point of view of the essential economics, the possibilities of control through air conditioning and the role of the physician in industry and in private practice Since many able-bodied men will probably be inducted into military service, industry may need to recruit workers from the physically handicapped and from the aging groups These developments, of enormous medical and social significance, will be featured at the congress Assignment of this type of worker into industry with proper consideration of physical ability and mental aptitude will be fully considered Concern has been expressed about the availability of trained personnel in industrial health, the subject of an early resolution by the Committee on Medical Preparedness of the American Medical Association A session will be devoted to determining what shortages exist and the best means for correction It is hoped that concrete proposals for better training for the industrial nurse, the industrial hygienist, the safety engineer and the physician in industry may grow out of these discussions A means will also be provided for the interchange of experience and results of recent activity by committees on industrial health in state and county medical societies

"The congress promises to provide an unusual opportunity to the medical profession to grasp a sense of its potential contribution to improved physical well-being among the employed population "

We cannot urge too strongly that all those who can arrange to do so attend the meetings of the congress For the information of all who are interested we are publishing the program on page 74

Fitness of Drafted Men

As men are called for the draft, it is inevitable that there will be many rejected as physically disqualified For years, physicians, educators, and many

others have collaborated on a campaign urging periodic health examinations Every facility has been offered which the ingenuity of man could devise to induce

public cooperation in such a movement. To which the public response has been Nuts!—or a reasonable facsimile thereof, such as the Bronx cheer.

So what? So now physicians in the New York area reject one-third of the men applying for Army service, and an earlier analysis of Navy volunteers shows 71 per cent of rejects. So the office boy leaves on our desk daily papers with headlines, for a joke or something, and some of our socialist acquaintances start right away to yell louder for State Medicine for the lack of which, if we don't have it right away, the country is going to hell. Also, Mr W Kaempfert of the *New York Times* cries "Dear, dear, alack-a-day, all is lost save group medicine," in meticulously correct English.

So the viewers-with-alarm, the head-shakers, the fingervaggers, and the whither-are-we-drifting grifters sharpen their pencils and wet their pens and drink black coffee so they can give medicine the works. Hence it looks like a natural from the publicity angle for the State Medicine boys and the jolly scribes.

However, as the facts gradually sift in between the headlines we find that a good many of the local draft boards have been passing men who have then been turned down by the army examiners. A large number of these rejects have been found to be psychologically unfitted for combat service. This is not to any great extent a remediable defect, but it can be a costly one for the government. Men are being accepted for training for one year now, and thereafter will constitute the Army reserve for nine years. Service-connected disability contracted during those years constitutes a lien on government pensions and hospital and medical care. For this reason army standards of acceptance are being kept as high as possible, far higher than would be the case if the Nation were at war and could not be so meticulous by choice.

There is reason to believe that we are far healthier now than at the time of the last war. Tuberculosis, for instance, has declined as a cause of mortality 75 per

cent more or less in the last twenty-five years, "among men of draft ages insured in the Industrial Department of the Metropolitan Life Insurance Company."

At the draft ages the reduction in heart disease mortality has been 40 per cent for white and 60 per cent for colored men between 1911-15 and 1939.

As an indication of health conditions at ages 25 to 44 the mortality of white policy holders has decreased by two thirds—from 11.1 per 1,000 in 1911, to 3.6 in 1939. The most substantial contribution toward the reduction in the total mortality rates comes from the marked improvement in the death rate from tuberculosis. The death rates (from 1911 to 1939) per 100,000 fell from 509.0 to 61.8 for white males and from 277.1 to 40.6 for white females. The mortality from syphilis, appendicitis has fallen markedly. The death rates for the group under review, per 100,000 for organic heart disease among white males, have dropped from 61.9 in 1929 to 50.2 in 1939, for cerebral hemorrhage from 12.0 to 10.6, and for chronic nephritis from 28.6 to 15.3.¹

Thus, in certain respects there need be no serious concern about the present health conditions of the nation between the ages of 25 and 44. The defects for which men are being rejected by the Army examiners are those structural and psychologic weaknesses upon which the strenuous nature of field training could be expected to have a detrimental effect. The point of view of the Army and of civilian medical examiners might be expected to vary considerably concerning the acceptability of certain risks and thus to account for the high percentage of rejections. They should not be taken too seriously in our belief, even by constitutional pessimists. And, after all, what can be done for flat feet, bow legs, and perforated eardrums?

HEALTH INSURANCE VERSUS SICKNESS INSURANCE

COLUMBIA UNIVERSITY COLLEGE OF PHYSICIANS AND SURGEONS

DE LAMAR INSTITUTE OF PUBLIC HEALTH
600 West 168th Street, New York*To the Editor*

I hope that in the future you will not allow articles dealing with sickness insurance to appear under the deceptive and fallacious title of health insurance

Also in editorials I believe it wise and correct to use the term sickness insurance when discussing the voluntary or compulsory type

There is no such thing as health insurance offered anywhere, nor can there ever be in the nature of things

It would help to prevent the laity kidding itself about health which is popular, front-page

stuff when they should be getting down to basic facts of insurance to meet the cost of medical care in sickness

December 5, 1940

Yours, as always,
HAVEN EMERSON, M D

[*Touché!* Since we agree thoroughly with the points made by Dr Emerson we must admit that we have fallen into the all too common error of using these terms in loose fashion This is an instance in which precision in language is most important—*Editor*]

TREASURY DEPARTMENT BUREAU OF NARCOTICS
NEW YORK, N Y*To All Members of the Medical Profession in New York City*

For some time there has been an acute shortage of illicit narcotic drugs available to the underworld in New York City Numerous narcotic addicts have undergone involuntary cures because of their inability to secure drugs In many such cases the withdrawal of drugs has not been particularly difficult for the reason that no great tolerance has been established by the use of the extremely diluted narcotics which the addict was able to obtain in the illicit traffic

Other addicts and dealers in illicit narcotics have been resorting to the medical profession in an endeavor to secure narcotics for addiction purposes and sale Many of these persons are skilled in simulating symptoms of illnesses for which narcotics are prescribed, some suggest to the physician that he prescribe for them an initial large supply of drugs for an "ambulatory reduction treatment" and by going from physi-

cian to physician have been able to acquire a substantial supply of drugs for the gratification of their addiction and for sale to others Most of these addicts are of the criminal type, many of them are adept forgers and may steal the physician's prescription blanks for the purpose of forging narcotic prescriptions if these blanks are within reach in the doctor's office

Present conditions are such that it is believed the physician is justified in using extreme caution in dealing with any stranger who might approach him in the manner described

This circular is issued as informative and in the hope that our mutual efforts may keep at a minimum the amount of drugs available to the illicit narcotics traffic

Very truly yours,
GARLAND WILLIAMS,
District Supervisor

CONFERENCES ON THERAPY

To the Editor

I believe that the conferences on therapy that you propose to publish from time to time will serve a very useful purpose and judging by the present one on fever it is evident that the subject is to be presented in a scientific manner and from a practical standpoint

I write you this letter with the idea in mind that discussions of the subject should be continued by your readers in such letters as this

My training dates back to the day when therapeutics was much stressed and it is my impression that within recent years therapy, except for a few specifics, has been relegated to a posi-

tion unworthy of its importance I am in hopes that the publication of conferences on therapy will aid in restoring this subject to its proper place

Regarding fever, it has been my impression that toxemia whether it be bacterial, metabolic, chemical, or thermal in nature is the direct cause of temperature response owing to its effect on the temperature center in the brain and it would seem that the resulting fever not only registers the defensive mechanism of the organism, but also the extent of the toxemia to which that organism is subjected All means at our command should

be used in counteracting this toxemia and, among these, excessive fluids are extremely important to make up for body loss of fluid in fever as well as to dilute circulating toxins so that the effect on other organs such as the kidneys may be minimized. In bacterial diseases I have always felt that drugs (and these include quinine, acetphenetidine, salicylates, etc.) play a very important part. It has been my impression that these drugs act not only on the temperature center but rather do they have a direct effect in controlling the growth of bacteria by which the production of toxins is reduced to a minimum and nature can then rid the body of these toxins

already present. This is entirely my bedside impression of the action of these drugs and yet for practical purposes their use has stood me as well as many others in good stead.

I hope that other readers will give their ideas pro and con on this subject and that a discussion may be stimulated which will, I am sure, serve a very useful purpose.

May I congratulate you and the discussers in the conferences on the able way in which the management of fever was presented.

Yours very truly,

MONROE B. KUMSTLER, M.D.

ERRATUM

Attention has been called to a regrettable mistake in the December 15, 1940, issue page 1814. In the article on the Medical Expense Fund of New York, Inc., it was stated that the *New York Herald Tribune* had published an editorial entitled "Another Medical Plan." This editorial appeared not in the *New York Herald Tribune* but in the *New York Times*—Editor.

WINTER IN ENGLAND—WHAT WILL IT BE LIKE?

Great Britain has made no secret of its fear of widespread epidemics in the cold, wintry months ahead. Crippled water supply systems, damp air-raid shelters, shattered homes, and bombed hospitals contribute to the growing menace of sickness and disease. Britain's limited store of medical and surgical equipment is being dangerously depleted.

Britain's Civilian Wounded Are Crying for Your Help!

The Medical and Surgical Supply Committee of America, with headquarters at 420 Lexington Avenue, New York City, composed of more than 265 physicians and surgeons in principal cities throughout the United States, is calling upon all doctors and their friends to contribute toward purchasing 1,000 emergency operating sets in khaki canvas rolls and 1,000 fitted first-aid metal cases to be shipped to Great Britain.

The price, insurance and delivery of these units to England is

1 emergency operating unit	\$200 00
1 first-aid fitted case	\$ 70 00

Each set will bear a plate with the donor's name, if desired.

PLEASE SEND YOUR CONTRIBUTIONS TODAY TO ARTHUR KUNZINGER
TREASURER, MEDICAL AND SURGICAL SUPPLY COMMITTEE OF
AMERICA, 420 LEXINGTON AVENUE, NEW YORK CITY

Suggestions for Contributors to the NEW YORK STATE JOURNAL OF MEDICINE

The NEW YORK STATE JOURNAL OF MEDICINE asks its contributors to follow the suggestions listed below in the preparation of their articles. In this way they will greatly facilitate the expeditious publication of the JOURNAL. These suggestions have been devised in order to save correspondence, avoid return of papers for changes, minimize the work of preparation for the printer, and save the high costs of corrections made on galley proof.

Size of Articles—It is earnestly desired that scientific articles shall not exceed ten JOURNAL pages at the outside. Even that number of pages tends to lower reader interest. An average of five or six seems to be the most desirable from this point of view. Calculation can readily be made by multiplying the number of double spaced typewritten manuscript pages by the fraction two-fifths.

Manuscripts—Papers must be typewritten on one side only of white sheets consecutively numbered, and be double spaced with one-inch margins. They should be prepared with great care so as to be typographically correct. All headings, titles, subtitles, and subheadings should be typed flush with the left-hand margin.

Titles—The title should be *brief* and typed in capital letters. The subtitle can be longer and should be typed in cap and lower case letters. Under the title, or subtitle, if there is one, should appear the name of the author and city in which he lives.

Subheadings—Subheadings should be inserted by the author at appropriate intervals.

References—It is the unfailing practice of the NEW YORK STATE JOURNAL OF MEDICINE to use specific "references" rather than "bibliography." There should appear in the text reference numbers, typed above and to the right of the word to which there is a reference. A list, consecutively numbered, should include the following items:

- a. **Books**—author's surname followed by initials, title of book, edition, location and name of publisher, year of publication, volume, and page number. Thus, Osler, W. *Modern Medicine*, ed 3,

Philadelphia, Lea & Febiger, 1927, vol 5, p 57

- b. **Periodicals**—author's surname followed by initials, name of periodical, volume, page, month (day if necessary), year of publication. Thus, Leahy, Leon J. *New York State J Med* 40: 347 (Mar 1) 1940.

NOTE: The JOURNAL does not include titles of articles.

Case Reports—Instead of abstracts of hospital histories, authors should write these reports in a narrative style with properly completed sentences. All unimportant details should be deleted with such general negative statements as *fit the case*.

Tables—While tables are very useful on lantern slides in the reading of papers, they fall of this purpose to a large extent in the printed page. For that reason it is urged that they be incorporated in the text.

Illustrations—These should be kept to the minimum necessary to make clear the points to be registered by the author. In some instances they are imperative to proper understanding, in others they are merely picturesque.

Where illustrations are to be used they should accompany manuscripts and each should always be referred to in the text, preferably by number. Drawings or graphs should not be larger than 12 × 16 inches, and must be made with jet black India ink on white paper or tracing cloth. *Do not use typewriter for lettering.* The smallest lettering on 8 × 10 inch copy should be no less than 1/4 inch high. Cross-section paper (white with black lines) may be used, but should not have more than 4 lines per inch. If finer ruled paper is used, the major division lines should be drawn in with black ink, omitting the finer divisions. In the case of finely ruled paper, only blue-lined paper can be accepted. Lettering and all markings must be large enough to be readable after reduction. Mail rolled or flat. Photographs should have clear black and white contrasts and be on glossy white paper.

Whenever possible "crop" photographs, i.e., mark portion that can be excluded when reproduced. Crop marks should be on *margin* of photographs—not on the photographs.

It is important to mark the top of the illustration on the back, also its number as referred to in the text, thus, Fig 1, 2, and the name and address of the author.

Legends should be typewritten on one sheet of paper and attached to the illustrations.

THE MEDICAL RESERVE OFFICER OF THE UNITED STATES NAVY

COMDR ERNEST R. EATON, MC-V(S), * USNR, New York City

[This article is particularly timely because of the Navy's dire need of doctors (see announcement on page 66—EDITOR)]

SEVERAL months ago the President of the United States urged Congress to act speedily in regard to the matter of compulsory military training and intimated that before long the medical profession at large would be required to meet the need of the progressively increasing number of citizens who would be called from civilian life into active military service in behalf of our country. The first peacetime compulsory military training in the history of the United States is now an accepted fact.

Because of emergency measures the United States Navy has increased from approximately 175,000 to 225,000. This increase necessitates additional commissioned medical officers. At the present time there is an opportunity for officers of the Medical Corps of the United States Naval Reserve to enter active service.

The maintenance of good health of the Navy personnel is the ultimate objective of the Medical Corps of the United States Navy. Briefly, this objective is reached by the following means:

- 1 The maintenance of a high standard of health and physical fitness of all
- 2 The care of the sick and of the wounded in battle
- 3 The dispensing of immunizing agents, especially smallpox and typhoid vaccination to the personnel
- 4 The administering of prophylactic agents
- 5 The instruction of personnel in matters of first-aid treatment, hygiene, and sanitation
- 6 The maintenance of health records of officers and men
- 7 The annual physical examination of all officers for the conservation and promotion of their health and to determine their fitness to perform all the duties of their grade at sea

- 8 The care, management, and custody of hospitals, ambulances, and medical and surgical supplies
- 9 The sanitation of ships, buildings, and grounds
- 10 The care of water supply, food, and clothing
- 11 The making of suitable recommendations to improve conditions of health of the officers, such as exercises ordered for the conservation of health. These consist of regular physical exercises taken by all officers in the open air for thirty minutes daily.

An officer of the Medical Corps of the United States Naval Reserve, when the time comes for him to be assigned to active duty, will be required to cooperate in carrying out the preceding plans, and he must fulfill his duties in regard to these plans in the same manner as would befit a medical officer of the Regular Navy. The Medical Officer of the Naval Reserve who is called to active duty must be prepared to do his work in an earnest manner, endeavoring to enter into his duties as though he had been trained from his earliest years in discipline and efficiency, doing what he is told to do, going where he is told to go, and in general following Navy customs, traditions, rules, and regulations.

An officer of the Regular Navy is not lacking in his duty to, and his understanding of, the Naval Reserve officer, and when asked for help and advice he will give assistance in a generous and courteous fashion. The Navy knows that efficiency means self-reliance and initiative and will seek to develop these important qualities in the officer of the Medical Corps of the Naval Reserve in active service. There are many sound principles in the Navy but none so deserving of such high commendation as the Navy sense of comradeship and desire to help others in their loyalty and efficiency. Especially is this true with respect to those who seek knowledge in their work from those in command.

A conspicuous and fundamental feature of our governmental policy is the maintenance of our Navy to uphold the United States in its national and international trade and to protect the territorial possessions of the United

* Medical Corps—Volunteer Reserve (Specialist Duty)
Organizer of the Long Island Naval Reserve Hospital,
Unit Number 15 Third Naval District

States The defense of our coast is an important part in the preparation of naval war plans, and included in this plan is a definite service expected of officers of the Medical Corps of the Naval Reserve

The United States Naval Reserve was conceived in 1916 and reorganized in the years of 1925 and 1938 It is a constituent part of the United States Navy Naval Reserve officers are commissioned by the President to serve in the same grade and rank as officers of the Regular Navy Appointments are made in conformity with the law enacted by Congress which made the Naval Reserve a component part of the Navy, with prescribed rules and regulations administered by the Secretary of the Navy

The Bureau of Medicine and Surgery maintains a complete medical record of all the personnel of the Navy, Marine Corps, and Naval Reserve It was created by an act of Congress on August 31, 1842, maintains hospitals, supply depots, medical laboratories, dispensaries, and technical schools for the Medical, Dental, and Hospital Corps, and is charged with the administration of the Nurse Corps Furthermore, it is allied with the Red Cross and the Veteran's Bureau

The Surgeon General is the head of the Bureau of Medicine and Surgery and is appointed by our President for a term of four years The Bureau of Medicine and Surgery under the direction of the Surgeon General directly governs the Navy Medical Reserve, administering appointments, promotions, physical examinations, retirements, discharges, etc

Officers of the Medical Corps of the Naval Reserve in active duty are subject to the same laws, rules, and regulations as the officers of the Regular Navy A book of *United States Navy Regulations and Naval Instructions* is issued in accordance with the provisions of Section 1547 of the Revised Statutes of the United States for the government of all persons attached to the Naval Service This book states that all officers and other persons belonging to the Navy are directed and required to make themselves acquainted with the regulations which set forth the duty, responsibility, authority, distinctions, and relations of the various bureaus, offices, and individual officers each to the other

The task assigned to the Navy Medical Reserve Corps in war or in national emergency in peacetime is the medical and surgical care of the personnel of the Navy and Marine Corps This is comparable to the services

given in municipalities by physicians, dentists, nurses, pharmacists, and hospitals

The Navy Medical Center in Washington, D C, established by General Order No 70, dated June 20, 1935, is a unity organization that functions as a medical, diagnostic, and educational center directly under the control of the Bureau of Medicine and Surgery, with an officer of the Medical Corps of the United States Navy in command Originally the Medical Center consisted of two subordinate administrative units—namely, the United States Naval Hospital and the United States Naval Medical School The Dental School was organized as a distinct unit on April 1, 1936, under a separate subordinate command

These institutions afford to members of the medical and dental personnel of the Navy such courses of instruction as may from time to time be determined by the Bureau of Medicine and Surgery in keeping with the current needs of the service A competent staff of instructors is maintained, and officers of the Medical and Dental Corps, as well as enlisted personnel of the Hospital Corps, are ordered to duty for the purpose of attending these courses as the exigencies of the service may permit

The laboratories of the Navy Medical Center are available for members of the personnel who desire to undertake research work and for the examination of pathologic specimens Further, clinical diagnostic facilities in the Medical School are provided for use by the Medical Center and the service at large

An extensive medical library available for the Navy personnel is maintained at the Medical Center

During attendance at the school, be he officer or enlisted man, the student becomes familiar with the traditions and achievements of the Navy and is given a better understanding of the environment in which he must live and work Aviation medicine, gas warfare, and tropical medicine are taught, as well as the medical and surgical emergencies characteristic of and pertaining to Naval service Also, the newly commissioned officer is instructed in the intricacies of the paper work of the Navy, in the medical and personal equipment necessary for sea duty, and, in general, in the performing of the duties of a medical officer afloat

The Naval Reserve occupies an important place in plans for national defense, and definite duties and positions are assigned to it which it is not possible for the Regular Navy under its peacetime strength to execute or fill

The United States Naval Reserve is intended to augment the Regular Navy immediately upon the outbreak of war and, with the Regular Navy, bears the first brunt of battle with the enemy at sea

The primary aim of the Naval Reserve is to make ready beforehand a force of qualified officers and enlisted men who will be, and are, available for immediate mobilization in the event of a national emergency and who, together with the active and retired personnel of the Regular Navy, will be, and are, able to meet effectively the needs of the expanding naval establishment while an adequate flow of newly trained personnel is being established. It is a component part of the United States Navy and consists of the following: (1) the Fleet Reserve, (2) the Organized Reserve, (3) the Volunteer Reserve, and (4) the Merchant Marine Reserve.

1 The purpose of the Fleet Reserve is to provide in the initial stages of mobilization an available reserve of ex-officers and ex-enlisted men of the Regular Navy who may be utilized without further training to fill those billets requiring experienced personnel.

The officer personnel of the Fleet Reserve consists of both ex-commissioned and ex-warrant officers of the Regular Navy who have been discharged honorably therefrom after not less than four years of service therein and who, with their own consent, have been appointed in the Fleet Naval Reserve by the Secretary of the Navy in the permanent rank last held by them. In time of peace such officers who are kept in the Reserve receive a small salary or pay but are not obliged to perform training or drill duty during that period. These commissioned officers include both medical and dental officers, designated, respectively, MC-F and DC-F.

2 The desired object of the Organized Reserve is to provide a trained force of officers and men which, added to the qualified personnel from other sources, will be adequate in numbers and composition to complete the war organization of the United States Fleet. This class of the Naval Reserve consists of officers and men who are required to perform annual training and other duties and who shall be available for immediate mobilization. The officer personnel includes medical officers, both commissioned and warrant (including pharmacists) and are designated MC-O.

3 The purpose of the Volunteer Reserve is to prepare a force of qualified workers and men in such numbers that if added to the officers and men in other branches of the Re-

serve they will be adequate to fulfill the intent of the Naval Reserve. It is composed of those members of the Naval Reserve not assigned to the Fleet Reserve, the Organized Reserve, or the Merchant Marine Reserve, who are qualified or partially qualified for prescribed mobilization duties. In addition to commissioned and warrant officers and enlisted men, the Volunteer Reserve includes aviation cadets, midshipmen, and nurses.

The officers of the medical personnel may be summarized briefly as follows: (a) Medical officers, commissioned and warrant (including pharmacists), qualified for general duties afloat or ashore—designated MC-V(G). (b) Medical officers qualified for specialists duties—designated MC-V(S). (c) Commissioned dental officers qualified for general detail afloat or ashore—designated DC-V(G). (d) Commissioned dental officers qualified for specialists duties—designated DC-V(S).

Each Naval District has a quota of Medical Specialists Units composed of medical and dental officers of the Volunteer Reserve. These units are intended to provide groups of qualified medical and dental officers in time of war or of national emergency. These units may be assigned to hospital ships, station ships, or base hospitals as the staff thereof or to augment the staff of the Regular Navy.

Each Medical Specialists Unit is composed of eight medical officers and one dental officer of the Specialist Reserve group. In addition and at such time as these units are called into active service, six nurses of the Naval Reserve Nurse Corps are assigned to each unit in which their services are desired.

A Medical Reserve Specialists Unit is composed of the following specialists, one of whom serves as the "organizer" of the Unit: (a) surgeon, (b) ophtho-mo-otolaryngologist, (c) urologist, (d) psychiatrist, (e) internist, (f) roentgenologist, (g) clinical pathologist, (h) orthopedist, and (i) prosthodontist.

In each unit "alternates" for the various specialists are set apart in accordance with the quota limit in each district. "Alternates" is the term given in a Medical Specialist Unit for younger men who are qualified in the various specialties but who are not called for active service with the units unless circumstances prevent the principals from serving. However, in time of national emergency, provided their services are not required with the units, "alternates" may be transferred to mobilization stations as unassigned medical specialists.

In addition to the specialists units as designated above, Laboratory Research Units may, in time of war or national emergency, be allotted to hospital ships, base hospitals, or other medical department activities to prosecute laboratory research work as required. Each unit is made up of medical officers of the specialists class and twelve pharmacist's mates, Class V6, who are qualified laboratory research workers.

The Naval Reserve Nurse Corps is a part of the Volunteer Reserve and is composed of graduate, unmarried, female nurses, having registry in one or more states. The applicants must be citizens of the United States or its insular possessions, and by an acceptance of an appointment in the Naval Reserve they obligate themselves to serve the Navy in wartime or when a national peacetime emergency exists. If required to do so, they must serve throughout the war or until the national emergency ceases to exist.

4 The ultimate object of the Merchant Marine Reserve is to provide officers and men for service on merchant vessels and to provide officers directly connected with the operation and managements of such vessels when commissioned in the Navy. So far as practicable such officers and men will be assigned to duty in their own vessels.

The Merchant Marine Reserve is composed of those members of the Naval Reserve who follow, or who for three years followed, the sea as an occupation or those who are employed in connection with the seafaring profession. The commissioned personnel includes medical officers who are designated MC-M.

To retain his commission in the service and to advance in rank in his corps, it is essential that a medical officer of the Naval Reserve exhibit such active interest as may be possible under the circumstances. Whenever an opportunity offers itself—when appropriations are available or at his own discretion without pay—he should take training duty and attend lectures and conferences and prepare papers on specific subjects. Study assignments should be promptly completed.

The Navy provides certain courses of instruction for Naval Reserve officers. In the case of officers of the Organized and Volunteer Reserve, enrollment in these study courses is obligatory, the minimum requirement being a correspondence course in Navy Regulations. In addition to the correspondence courses in professional subjects the Naval War College conducts a special course in strategy and tactics for Naval Reserve officers. A reading

course also is provided by the Bureau of Navigation.

Candidates for appointment as medical officers in the Naval Reserve must be citizens of the United States and must be over 21 years of age. Medical officers in the classes MC-O, MC-V(G), and MC-V(S) may be appointed upon presentation of satisfactory credentials as set forth below, which may be accepted in lieu of a professional examination.

- (a) Letters or certificates from three or more persons of good repute testifying from personal knowledge to good habits and moral character of the candidate.
- (b) Certificate of medical education. This certificate must be from a Grade A school, give the date of graduation of the candidate, and be signed by the dean or registrar.
- (c) Certificate from the president or secretary of a state or local medical society to the effect that the applicant is a member in good standing.
- (d) Certificate of license to practice medicine.
- (e) Certificate from the proper hospital official indicating type and duration of internship.
- (f) If the candidate has had hospital service or special educational or professional advantages, certificates to this effect, signed by the proper authorities, should be forwarded.

In addition to the foregoing conditions of entrance into the MC-V(S) class, evidence of qualification in his specialty must be presented by the candidate.

The limiting border of ages for original appointments in the Naval Reserve are as follows:

	Organ- ized Reserve	Volun- teer General	Volun- teer Special (Mini- mum)	Mer- chant Marine
Commander			45	30-64
Lieut. Com- mander			37	27-62
Lieut.			31	24-60
Lieut. (J G)	21-32	21-32	25	21-44
Ensign	21-28	21-28	21	
Ensign (Prob- ational)		21-28		

The grade and rank in which candidates for class MC-V(S) are appointed is determined by the candidate's age, professional standing, and academic seniority. These must be appropriated to the duties of the mobilization assignment. After entrance into the Navy

service, the officer is automatically promoted to the next higher grade, providing he demonstrates an honest and earnest interest in the service to which he is attached and maintains a clear record as to naval offenses.

The pay of officers of the Naval Reserve on active duty is identical with that of the Regular Navy officers of equal rank and length of service. In addition to the base pay certain allowances are granted to officers not occupying government quarters and also to those officers who have dependents. The annual combined pay and allowances range from a minimum of \$2,199 for a newly appointed Ensign to a maximum of \$7,200 for a Captain, the highest rank attained in the Medical Corps of the Naval Reserve. The lowest grade in which a medical officer is appointed is that of Lieutenant (junior grade), with pay and allowances of \$3,158 per annum if married and not occupying government quarters. In addition to the preceding pay and allowances the Naval Reserve officers are granted a cash clothing allowance when first reporting for active duty.

The applicant must be proved to be physically qualified to perform the duties of his rank at sea and on shore by passing a complete and thorough physical examination. The standard of physical examination for Medical Reserve officers is the same as for officers of the Regular Navy. These standards exclude all pathologic conditions that would interfere with the performance of the duty required in the service or those that, as a result of service, may be especially liable to undergo progressive change or to become the basis of a claim against the government in the event of the officer being called in active service. Among these are (a) feeble constitution, general poor physique, or impaired general health, (b) any disease or deformity, either congenital or acquired, that would impair efficiency of the body or any of its organs or parts, and (c) any acute disease will be sufficient cause for rejection of an applicant.

Standards of physical examination are Eyes—12/20 in each eye unaided by lenses and capable of correction by lenses to 20/20, color—the applicant shall be required to read all plates in the color vision test book, hearing—15/15 whispered voice and 40/40 watch, height—minimum 66 inches, maximum 76 inches, weight—minimum 132 pounds (more than 15 per cent above the prescribed weight disqualifies an applicant), chest—minimum expansion of 2½ inches, and teeth—minimum of 20 vital, serviceable, permanent teeth of

which there shall be four opposing molars, two of which shall be on each side of the median line, and four directly opposed incisors.

In certain branches the physical examination is followed by a written one. After the applicants are passed, names are listed in the order of the examination marks received. Thus is determined the order of seniority. As already intimated, in the case of the MC-V(S), a written professional examination may be waived in lieu of the establishment of professional qualifications of the applicant, which qualifications are essential and are required by law to be submitted. Upon acceptance of a commission in the Medical Corps of the United States Naval Reserve, an officer agrees that in time of war and in a national peacetime emergency he will serve his country. Our President has declared that this present period of our history is a national peacetime emergency.

Information for persons desiring appointment as officers or for enlistment in the Medical Corps of the United States Naval Reserve is published in a circular by the Bureau of Medicine and Surgery, Navy Department. The titles and addresses of the commandants of the various Naval Districts to whom application may be made are as follows:

Commandant, 1st Naval District, Navy Yard, Boston (States of Maine, Massachusetts, New Hampshire, Vermont, and Rhode Island, including Block Island.)

Commandant, 3rd Naval District, 90 Church Street, New York City (States of New York, Connecticut, and upper New Jersey, including counties of Mercer, Monmouth, and all counties north thereof, also Nantucket Shoals Lightship.)

Commandant, 4th Naval District, Navy Yard, Philadelphia (States of Pennsylvania, southern part of New Jersey, including counties of Burlington, Ocean, and all counties south thereof, Delaware, including Winter Quarter Shoal Light Vessel.)

Commandant, 5th Naval District, Naval Operating Base, Norfolk, Va. (States of Maryland, Virginia, West Virginia, and the counties of Currituck, Camden, Pasquotank, Gates, Perquimans, Chowan, and Dare in North Carolina, also the Diamond Shoal Lightship.)

Commandant, 6th Naval District, Navy Yard, Charleston, S. C. (States of South Carolina, Georgia, and North Carolina, except the counties of Curri-

tuck, Camden, Pasquotank, Gates, Perquimans, Chowan, and Dare)

Commandant, 7th Naval District, Navy Yard, Charleston, S C (States of Florida, counties of east of Apalachicola River, Alabama, Tennessee, Louisiana, Mississippi, Arkansas, Oklahoma, and Texas)

Commandant, 8th Naval District, Navy Yard, Charleston, S C (States of Florida, counties west of Apalachicola River, Alabama, Tennessee, Louisiana, Mississippi, Arkansas, Oklahoma, and Texas)

Commandant, 9th Naval District, Naval Training Station, Great Lakes, Ill (States of Ohio, Michigan, Kentucky, Indiana, Illinois, Wisconsin, Minnesota, Iowa, Missouri, North Dakota, South Dakota, Nebraska, and Kansas)

Commandant, 11th Naval District, Naval Station, San Diego, Cal (States of New Mexico, Arizona, southern part of California, including counties of Santa Barbara, Ventura, Los Angeles, and San Bernardino, and all counties south thereof)

Commandant, 12th Naval District, San Francisco (States of Colorado, Utah, Nevada, northern part of California, including counties of San Luis Obispo, Kern, Inyo, and all counties north thereof)

Commandant, 13th Naval District, 553 Federal Building, Seattle (States of Washington, Oregon, Idaho, Montana, Wyoming, and Territory of Alaska)

Commandant, Navy Yard, Washington, D C (Washington, D C)

Whether the duty be that of Medical Officer afloat or ashore, the following instructions prepared by the present Senior Medical Officer of the Third Naval District will be of value in giving a general outline of the procedure to be followed by officers reporting for duty The list covers most of the points to be considered when reporting on board a large-type vessel The list would be condensed and some points omitted when reporting on board a destroyer or a similar vessel

- 1 When reporting on board in civilian clothes, have uniform, sword, and gloves in luggage with you
- 2 Report to the Officer-of-the-Deck Give him a copy of your official orders for record in the ship's log
- 3 Obtain your stateroom assignment The First Lieutenant of the ship usually is in charge of assigning officers'

rooms Normally, the Officer-of-the Deck will either obtain this information for you or have his messenger escort you to the First Lieutenant's office

- 4 Change into uniform
- 5 Report to the Executive Office with your orders The Executive Officer will give you brief instructions covering your duty on that vessel and usually will give you instructions in regard to time and uniform for calling on Captain
- 6 Turn in your orders to the Ship's Secretary in the Captain's office for endorsement
- 7 Report to Senior Medical Officer
- 8 Stow clothes and outfit (or have mess attendant stow) in stateroom
- 9 Obtain combination of your room safe from First Lieutenant Reset combination
- 10 Obtain linen for bed and blankets from First Lieutenant
- 11 Pay mess entrance fee and mess bill to Wardroom Mess Treasurer
- 12 Purchase a share in Cigar Mess from Cigar Mess Treasurer (optional)
- 13 Draw *Ship Organization Book*, *Ship's Battle Organization Book*, and any other ship's instructions from Ship's Secretary Stow same in stateroom safe
- 14 Learn your station and duties for general quarters, fire quarters, abandon ship, quarters for master, collision quarters, fire and rescue, and other emergency exercises for which bills have been prepared on that ship
- 15 Learn ship's daily and weekly routine
- 16 When your orders are returned to you by Ship's Secretary after having been endorsed by the Captain, take them to the Disbursing Officer with Transfer Pay Account in order to be taken up on the payrolls of that vessel If first reporting for active duty, you will not have a transfer pay account, and it will be necessary for the Commanding Officer to write an order to the Disbursing Officer directing the latter to take you up on the payrolls
- 17 Furnish Disbursing Office with original orders and required numbers of copies for payment of travel allowance

The preceding observations are not to be construed as official or reflecting the views of the Navy Department or the Naval Service at large Divested so far as possible of techni-

calities, principal points of information have been emphasized in the hope that if the reader does not find the information too disconnected

he may be helped in better understanding the Medical Officer of the United States Naval Reserve
53 West 83rd Street

OSLER WAS AN OBSTINATE MAN

So declared Dr. Joseph McFarland, who spoke on "Osler as I Knew Him" at the dedication of the Osler Memorial Building at the Philadelphia General Hospital, "Old Blockley," on June 8. "Osler at Old Blockley," Dean Cornwell's oil painting depicting a scene during the beloved physician's career while at Philadelphia General Hospital, was given its first public showing at the dedication. The painting was also shown, together with "Beaumont and St. Martin," Cornwell's earlier medical painting, at the American Medical Association meeting in New York. "Osler at Old Blockley" is the second in the series, "Pioneers of American Medicine," which is being produced by John Wyeth & Brother, Inc., of Philadelphia, to dramatize the contributions of Americans to the advancement of medicine.

The old "Post House" in which Osler performed many autopsies during his Blockley years had been unused for twenty years. A committee of Blockley graduates decided to restore it to its original state and maintain it as the first American memorial to the famous Dr. William Osler. A grant from John Wyeth & Brother, Inc., enabled its completion.

More than a thousand physicians gathered on the grounds of Philadelphia General Hospital for the dedication.

Osler was not only obstinate, recalls Dr. McFarland, as reported in the *Medical Record*, but his views were 'frequently brought out with the added force of irony and sarcasm.'

"For example, I remember one of his bedside talks. All of his teaching was at the bedside, the bed being wheeled into the lecture room before the whole class of students in the University Hospital, or a group of students going into the ward with him in the Blockley Hospital. This lecture was on cirrhosis of the liver. We had an advanced case with ascites and also marked circulatory obstruction, and after all phases of the disease had been dwelled upon and the treatment reached, he turned to one of the students and said, 'Now, what shall we do for this man?' The student, remembering the instruction received in other departments, unhesitatingly responded, 'Administer potassium iodide to absorb the connective tissue of his liver.' Assuming an erect and somewhat belligerent attitude and emphasizing each word with an extended forefinger, Osler said, 'You might as well administer iodide of potassium to absorb a lead pencil in the man's vest pocket as to absorb the connective tissue in his liver.'

These words I have never forgotten, though I do not remember what, if any, treatment was prescribed. He probably recommended no medication of any kind. Indeed that was his usual method. Keep the patient in bed, carefully regulate his diet, keep his bowels comfortably

moving, were apt to be his only recommendations. This led to the charge that he was a therapeutic nihilist, that he only studied his patients and did not treat them, and brought upon his head the execration of those members of the class who had begun to study medicine through pharmacy and working in drugstores, serving as drug clerks, all of whom knew a large number of elegant formulas, of much greater advantage to the pharmacist than to the patient, and who came into the profession because they believed that practice consisted of the administration of drugs.

"It was difficult to understand some of Osler's attitudes, especially toward the cardiac cases. In all of the other clinics, and by almost every other one of our teachers, every case of cardiac disease was immediately given digitalis. Osler pronounced it digitalis and used it very sparingly. His remedy for most cases was rest in bed, careful diet, and tincture of cardamom compositus. He was accustomed to say, 'What this heart needs is rest and food. It doesn't want to be whipped up and driven to further exhaustion.' And in regard to the cardamom he said, 'It is pleasing in appearance, has a pleasant odor, a distinctive aromatic taste, is readily accepted by the patient and does neither harm nor good. Give it until you find out what else it may be desirable to do.'

'He was also insistent upon not treating the patient until you knew what ailed him. This principle was once carried so far that it almost brought about his expulsion from Blockley. It was in 1880, only five years before, that Laveran discovered the plasmodium of malaria, and I suppose that its announcement in this country was received with the same widespread skepticism as the tubercle bacillus. During my whole course in medicine I never saw anyone who looked for it in the blood as a curiosity or sought for it for the purpose of making a diagnosis of malarial fever. Let me add in passing that at the time of which I speak the microscope was scarcely used in clinical medicine except for the examination of urinary sediments. But Osler took his microscope into the hospital wards and searched the blood of all fever patients for malarial parasites, or whatever else he might find, giving them no quinine when no parasites were found, continuing to examine the blood from day to day, often delaying the administration of the specific until he had studied all phases of the cycle of parasitic development.

'The Guardians of the Poor considered it an unpardonable neglect of the sick poor and arranged to let Dr. Osler know that if he continued such careless practice he would be requested to yield his position to someone else. He, however, continued in much the same way, he was an obstinate man.'

ENTEROPATHY IN DEFICIENCY STATES

DAVID ADLERSBERG, M D , and MICHAEL WEINGARTEN, M D , New York City

IT HAS long been known that nutritional deficiency produces functional and organic changes in the gastrointestinal tract. The clinical picture of a deficiency state is frequently the result of deficiency of more than one factor. For instance, cases of beriberi often present symptoms of scurvy and pellagra. In pellagra and in beriberi, fatty stools, so characteristic of sprue, may be observed. A person affected with pellagra may show scorbutic symptoms as well as evidences of vitamin A deficiency.

While the fully developed clinical pictures of avitaminosis involving the gastrointestinal tract (sprue and pellagra) are relatively infrequent in this part of the country, there can be little doubt that milder, subclinical forms occur with great frequency. Yet relatively little emphasis has been placed on the recognition of these subclinical deficiencies, especially insofar as they manifest themselves through gastrointestinal symptoms. This is probably due to the lack of definite criteria for the diagnosis of these conditions. The recognition of subclinical scurvy has been greatly aided by the availability of a quantitative chemical determination of vitamin C in the blood and urine. Unfortunately, there are no simple laboratory procedures available at present for the determination of the various components of the vitamin B complex in the body. Here the recognition of a subclinical deficiency has to be based solely on the clinical analogy to the classic deficiency states with prominent gastrointestinal symptoms.

It is our belief that many patients who do not present the well-defined pictures of sprue and pellagra are, nevertheless, suffering from milder forms of nutritional deficiency. This belief is based on the similarity of symptoms and of roentgenologic findings, particularly in the small intestine, and the therapeutic response to the same agents that favorably influence the course of sprue and pellagra. The study of this problem has led us to believe that it is the explanation for many obscure and frequently undiagnosed gastrointestinal conditions. We have found signs of deficiency in patients whose gastrointestinal tract was

injured by mechanical, chemical, or infectious agents that impaired absorption or as a result of improper nutrition per se. Prolonged dietary insufficiency, alcoholic excess, the roughage fad, and irrational reducing diets are among the producing causes. Impaired gastric function with achylia, or after gastric resection or gastroenterostomy, and organic disease of the stomach or colon (notably ulcerative colitis¹) are predisposing factors. It will be recalled that the factors enumerated, when intensified and prolonged in their action, may produce the picture of "secondary pellagra."

In the advanced case of sprue and in well-developed pellagra, the intestinal symptoms are very similar: diarrhea, distention, flatulence, borborygmi, and vague abdominal pains. In pellagra, spruelike stools have been described, and we have observed microscopic evidence of impaired fat digestion in our cases. The advanced case of sprue is characterized by a marked steatorrhea, but it must be remembered that some milder cases of sprue with otherwise typical manifestations of the disease may have no anemia or diarrhea, and, during a remission, they may even be constipated, may have formed stools, and may show only microscopic evidence of impaired fat digestion (Miller and Barker²).

The cases of mild nutritional deficiency which we have observed have at no time during their course shown the fully developed picture of sprue or pellagra. It is difficult, therefore, to classify them with either of these entities, although it may be possible to consider some of them at least as a "forme fruste" of one of these diseases. Most of the cases, however, do not lend themselves to even such a designation and must, in the present state of our knowledge, be considered cases of "nutritional deficiency involving the gastrointestinal tract."

Clinical Picture

The chief complaints are a feeling of heaviness and distention in the abdomen with a marked increase in gas formation, borborygmi with "splashing, gurgling noises" in the abdomen, belching, and flatulence. There is a sense of abdominal unrest and pain which varies in intensity from mild to cramplike sensations, which are usually localized in the

Presented in part at a joint meeting of the Section on Gastroenterology and Proctology and of the Section on Radiology of the A. M. A., St. Louis, May 19, 1939.

From the Gastrointestinal Service (Dr. H. A. Rafsky) of Beth Israel Hospital.

umbilical region Nausea may occur a few hours after meals, and poor appetite is frequent Constipation is often present, but the bowel movements may be regular with either formed or semiformal stools However, diarrhea may occur, especially when the fat and roughage intake are excessive Glossitis may be present Denudation of the epithelial lining, superficial ulcerations, varying degrees of swelling of the tongue, and disturbance of taste are found Fissures and scaling of the corners of the mouth (cheilosis) may also be found Neuritis of the peripheral type, as well as other signs of deficiency, may be associated

It often happens that these patients have for years been regarded as neurotics or that they have been treated for peptic ulcer, gastritis, chronic appendicitis, or "spastic colitis" Nevertheless, this form of deficiency may be associated with gastritis, peptic ulcer, gallbladder disease, and the various forms of colitis

The stools (formed, semiformal, or loose) contain large amounts of fatty acids and soaps In evaluating this, it is important that the total daily intake of fat is not excessive (about 80 Gm), because, if large amounts of fat are taken even by a normal individual, there will be a certain amount of unabsorbed fat in the stool Also, it is necessary to rule out the presence of pancreatic disease In the latter case the stools are characteristically more bulky, and the fat is chiefly in the form of unsplit, neutral fat

Roentgenologic Findings

On roentgenologic examination, gastric atony is a frequent finding Hypermotility, but more often hypomotility, of the small intestine may be observed In either case there is an irregular, smudged filling of the coils, and deep spasms and peristaltic contractions may be observed, both fluoroscopically and roentgenographically Instead of the smooth, continuous filling normally observed, isolated coils are found, and there are variations in the contours and caliber of the intestinal segments Dilated as well as narrow loops are seen Occasionally, a loop may be so markedly dilated as to simulate the colon in appearance The mucosal pattern is thickened in the narrowed loops and shows disappearance of the markings in the dilated loops Such changes have been described in cases of sprue by Pillai and Murthi,³ and Snell and Camp,⁴ and in pellagra by Weber and Kirklin.⁵ Mackie and Pound¹ have found them in

Fig 1 Pellagra, white male, aged 24. Mental changes, typical dermatitis, diarrhea Small intestine four hours after barium meal dilated, narrowed, segmented and isolated loops Hypersecretion and gas

a series of cases of ulcerative colitis and have related them to the deficiency state

It is necessary to exclude the effect of drugs before interpreting the small intestinal picture For example, a saline laxative may produce changes in the appearance and increase the normal motility On the other hand, morphine produces delayed motility and gas in the small intestine for twenty-four hours and sometimes as long as five days (Pendergrass⁶)

Two factors are apparently concerned in the disturbance of motility observed (1) the irritation of the intestinal mucosa tending to cause hypermotility and (2) the alteration of the neuromuscular control which tends to produce hypomotility and hypomotility of the entire gastrointestinal tract The resultant of these two factors determines the final motility of the small intestine, so that we may have cases of hypermotility, hypomotility, and even normal motility associated with very definite signs of small intestinal involvement It should also be remembered that the gastric and colonic motility may influence the emptying of the small bowel Atony and dilatation of the colon with large amounts of gas may be observed

The changes in pattern and motility of the small intestine found in deficiency states may also be present in inflammatory, granulomatous or neoplastic lesions, and in steatorrhea of pancreatic origin They are by no means specific Nevertheless, they form an important part of the syndrome of deficiency as it affects the gastrointestinal tract and are of special value as a diagnostic lead in milder states of deficiency (see figures)

FIG 2

FIG 2 Deficiency syndrome with nutritional enteropathy, restricted diet for many years, sciatic neuritis, occasional diarrhea, large amounts of fatty soaps and acids in stool Small intestine two hours after barium meal patchy filling of jejunum, segmented, dilated, narrowed loops

FIG 3

FIG 3 Deficiency syndrome with nutritional enteropathy, restricted diet due to gallbladder disease and "nervous indigestion", flatulence, distention, vague periumbilical pains, glossitis, neuritis Small intestine three and one-half hours after barium meal patchy filling, irregular contours, segmented loops

Discussion

A consideration of the possible cause of the changes found in the subclinical deficiencies may well begin with a discussion of the observations made in sprue and pellagra

Pathology of the Gastrointestinal Tract in Deficiency States—It is now universally accepted that pellagra and sprue are primarily due to nutritional deficiency The pathologic changes in the gastrointestinal tract in both diseases show striking similarities Glossitis is a common feature

In pellagra, MacNeal⁷ has described "an inflammation throughout the intestine, patchy in distribution Strips of hyperaemic intestine several feet in length alternated with strips fairly normal in appearance" Vascular engorgement, hyperplasia of lymphoid tissue, edema, and infiltration of the mucosa with wandering cells were seen Loss of superficial epithelium was extensive, ulceration commonly occurred in the lower ileum, caput coli, and rectum Lynch,⁸ describing similar changes, asserts that "the state of the intestine described is the outstanding structural change in pellagra It constitutes thus far the only visible characteristic evidence of the disease, except the dermatitis, at post-mortem examination"

In sprue, Faber⁹ and Manson-Bahr¹⁰ held that the essential pathologic change is an in-

flammation of the intestinal wall especially involving the small intestine Faber was able to show the presence of diffuse and sometimes ulcerative enterocolitis in sprue His findings were confirmed by Manson-Bahr, who states that "evidence is accumulating that the essential primary lesion of sprue is an ulceration of the small intestine chiefly affecting the lower end of the ileum" The findings in a typical case were catarrhal changes in the duodenum and hyperemia and ulceration of the lower jejunum and ileum Microscopically, there was atrophy of the villi due to fibrosis, diffuse round cell infiltration of the whole mucosa, and general fibrosis of the submucosa Justi,¹¹ Fischer and von Hecker,¹² and Reed¹³ report similar findings in cases of sprue

On the other hand, Thaysen¹⁴ is an exponent of the view that the intestinal changes observed in sprue are variable and that sprue may persist for a great number of years without organic findings He, as well as Macke and Fairley,¹⁵ interprets the intestinal wall changes found in some cases as being of a secondary nature, either produced by invasion of microorganisms of low virulence or by an irritation of the mucous membrane by the abnormal intestinal contents More recent examinations of cases of nontropical sprue by Rosenthal¹⁶ and Luksch and Sachs¹⁷ showed definite chronic inflammatory changes

FIG 4. Nutritional enteropathy following gastric resection for duodenal ulcer, restricted diet due to residual pain, bloating, distention, flatulence, achlorhydria, no marginal ulcer. Small intestine immediate film, overloading of jejunum, dilated loops, two and one-half hours after barium meal. patchy filling, isolated coils, irregular contours

of the small intestine and cecum, with ulcerations and scar formations

In an experimental study on monkeys fed on autoclaved food, polished rice, and onions, McCarrison¹⁸ found congestive, necrotic, and inflammatory changes in the mucous membrane, sometimes involving the entire gastrointestinal tract, sometimes limited to areas of it, degenerative changes in the neuromuscular apparatus, resulting in dilatation of the stomach, ballooning of areas of small and large bowel, degenerative changes in the secretory elements, hemorrhagic infiltration, and atrophy of the lymphoid elements. Despite the importance of these observations, we have been unable to find any confirmation or denial of them.

Role of Vitamins—Consideration of the pathologic changes in sprue and pellagra, as well as in the experimentally induced deficiency states, may lead to the conclusion that the structural integrity and normal function of the gastrointestinal tract are dependent upon an adequate supply of vitamins. The vitamin B complex seems to be of particular importance but a normal supply of other vitamins is necessary. Vitamin A deficiency produces keratinization of epithelial structures with increased susceptibility to infection. This has been observed especially in the lacrimal glands, the bronchial tree, the renal pelvis, and also in the gastrointestinal tract. There are some experimental observations of changes in the gastrointestinal tract in vitamin A deficiency in animals.¹⁹ However,

there is no conclusive evidence of such changes in man in a pure vitamin A deficiency. Vitamin B₁ deficiency has been shown to produce hypotonicity and diminished motor activity of the entire gastrointestinal tract, possibly through its effect on the neuromuscular apparatus. The most striking clinical gastrointestinal symptom is anorexia. Deficiency of nicotinic acid is associated with pellagra and secondary pellagra. The improvement of the gastrointestinal symptoms of sprue upon the administration of liver extract rich in vitamin B₂, as well as the beneficial effect of liver extract and nicotinic acid on the diarrhea of pellagra, is well established. Certainly all the factors of the vitamin B complex are not known at present. A recent study indicates that an unknown nutritional factor, tentatively called "vitamin M," is necessary to prevent pellagra in monkeys in addition to nicotinic acid, riboflavin, and thiamin, and other known components of the vitamin B complex (Langston, Darby, Shukers, and Day²⁰). The nature and functions of the various components of the vitamin B complex are still in the process of evaluation. Recently, attention has been called to choline as a possible component of the vitamin B complex.

As to vitamin C, Einhauser²¹ found that it is stored in the walls of the small intestine and that in patients with gastrointestinal catarrh the utilization of this vitamin is impaired. It has been found easier to produce tuberculous infection of the small intestine in animals de-

prived of vitamin C than in the nonscorbutic controls (Greene, Steiner, and Kramer²³)

The steatorrhea and the negative calcium balance found in tropical and nontropical sprue and in celiac disease have been related to vitamin D deficiency. However, this apparent vitamin D deficiency may be secondary to a failure of absorption of fats and fat-soluble vitamins as a result of vitamin B₂ deficiency. The important role of vitamin B₂ in fat absorption has been emphasized by Verzar,²² based on the work of Mottram, Cramer, and Drew²⁴ and Cramer and Ludford,²⁵ who demonstrated the abnormal histologic picture of fat absorption in animals suffering from lack of vitamin B₂. However, this work has not been confirmed as yet.

Pathogenesis—Two modes of pathogenesis have to be considered in cases of deficiency involving the gastrointestinal tract.

1 A group of patients may show at first no symptoms of deficiency because the vitamin supply has been adequate. An irritation of the wall may result from mechanical, chemical, or infectious injuries to the gastrointestinal tract, and this may cause gastrointestinal dysfunction. Involvement of the small intestine results in an impairment of absorption of fats, carbohydrates, proteins, and vitamins supplied with the food. When the inflammatory process causes hypermotility of the small intestine, this factor in itself may impair the absorption to a great extent, since the absorptive capacity of the colon is very limited. In cases with a normal or delayed small intestinal motility, physicochemical changes due to the inflammatory process may, in themselves, alter the complicated mechanism of absorption of nutritional elements as well as of vitamins. The secondary deficiency thus produced diminishes the resistance of the tissues to further injury, giving rise to a vicious circle: primary irritation—secondary deficiency—further irritation (secondary to deficiency).

2 In another group of patients nutritional deficiency presents itself at the outset. Here we find those who have for a long time taken unbalanced modifications of various diets (e.g., Sippy, low residue, gallbladder, and colitis diets), persons suffering from alcoholism whose vitamin and food supply have been diminished by the caloric value of the consumed alcohol, and otherwise normal individuals who, due to misinformation or poor economic conditions, have failed to consume foods that are essential for an adequate vitamin supply. Here, a special role might be attributed to the vitamin B complex, the lack

of which may cause a disturbance in absorption of other vitamins, thus producing the picture of a polyavitaminosis with diminished resistance to infection and other noxious factors. The superimposed inflammation of the intestinal wall in this group is secondary to a primary nutritional deficiency and results from bacterial infection and irritation by abnormal intestinal contents. The vicious circle in this group presents itself as primary deficiency—secondary inflammation—further deficiency (secondary to inflammation).

Although the sequence of etiologic factors is different, the result is the same, and the final clinical and roentgenologic picture of both groups is that of a chronic enteropathy.

The concept of the relation of gastrointestinal disorders to nutritional deficiency presented here resembles a recent development in another field of medicine. The discovery that many forms of polyneuritis were related to vitamin B₁ deficiency led to the work of Weiss and Wilkins,²⁶ who demonstrated the not infrequent occurrence in this country of "beri-beri heart" in association with various forms of neuritis. Similarly, we find that changes in the small intestine resembling those found in both sprue and pellagra appear in association with other symptoms of nutritional deficiency in many patients with gastrointestinal symptoms.

In a previous publication we have referred to the small intestinal changes in deficiency as being due to a "chronic enteritis."²⁷ The use of the term *enteritis* in this connection appeared to us to be as justified as the use of the terms "glossitis" and "neuritis" to describe the lingual and neural changes found in association with deficiency. However, similar changes in the small intestine have been found in various types of steatorrhea. In view of this fact, of the controversy as to the actual changes in the intestinal wall in sprue and pellagra, and of the complete absence of anatomic examinations of the intestine in the milder deficiency states, we consider the term "chronic enteropathy" to be more appropriate. Whether the changes observed by us in the milder subclinical deficiency states are functional or organic in origin, they constitute a recognizable clinical and roentgenologic entity to which the term "chronic enteropathy" may be applied until further study permits a more exact evaluation of the basic pathology.

Therapy—The therapy of intestinal symptoms in deficiency states must attempt to break the vicious circle by attacking it at its

two poles inflammation and deficiency. It consists in the use of measures intended to alleviate the irritation of the intestinal wall and to supply an adequate amount of vitamins. The diet used is a high vitamin, high protein, low residue diet. In a group of cases, addition of lecithin to the diet exerted a favorable influence on food absorption (particularly fat, possibly vitamins) and on intestinal motility. Soy bean lecithin in amounts of 10 to 20 Gm daily was given. Whether this effect is caused solely by improved absorption or by the action of choline (in the lecithin) is under study.

Mild astringents, such as colloidal aluminum hydroxide preparations or bismuth subgallate, may be used. Liver extract and vitamin B₁ (thiamin chloride) should be given, preferably parenterally, because of the disturbed absorption. It is necessary to give large doses and for a long time. Treatment must not be discontinued even after the symptoms have improved, as there is a marked tendency to recurrence. Nicotinic acid and riboflavin have also been found to be useful in combination with liver extract and thiamin chloride.

Summary

Emphasis has been placed upon the recognition of subclinical deficiency states, especially insofar as they manifest themselves through gastrointestinal symptoms, thus resembling mild cases of sprue and pellagra.

Evidence of a chronic enteropathy as presented above should call attention to the possible existence of a deficiency state in the same way that a neuritis may furnish a clue

to the existence of a latent or incompletely evolved beriberi.

THANKS TO A DOCTOR

By ELIZABETH WILLCOX KIDWELL

It seems a very little thing
That still my child can sing,
That earth's small voices speak to her
The robin's call, the muted churr
Of locust through the meadow haze,
That yet her blithe and restless toes
Scorn the reluctant ground,
And still before me goes
Her wit's bright flame lighting the round
Of the slow wheeling days

It seems a very trifling thing
In a great world distraught,
And yet in ancient times a healer taught
That a child twice given
Is proof of heaven

DOCTOR'S WIFE HAS HER OWN TEN COMMANDMENTS

She must not know the meaning of the word "jealous"

She must never gossip

She must run a cafeteria, serving meals at all hours for her husband

She must be—like Caesar's wife—above reproach

She must have self-reliance and self-control

She must be able to think quickly and sanely in emergencies

She must be a diplomat, see all, hear all, say a lot, yet say nothing

She must learn to bear, stoically and without complaint, disappointments in her personal plans

She must be a good mother and father, because doctors are often too busy to discipline their own children.

She must be a good "doctor" because doctors never take time to doctor themselves

—Author Unknown, *Wichita Medical Bulletin*

THE CLINICAL FACTORS OF THE VITAMIN B CONTENT*

MORRIS L. DRAZIN, M D, Jackson Heights, Long Island, New York

"VITAMIN B" which at one time was thought to be a single vitamin is now known as a highly complex substance¹. At present a number of its constituents have been identified. However, it is fair to assume that further research will split the remaining portions into more fractions. The diagram (Fig. 1) illustrates the composition of the vitamin B complex.

There are two main divisions of the vitamin B complex, thermostable and thermolabile.

Thermostable

Chick dermatitis factor identified in 1935 (pantothenic acid)

Antigay hair factor identified in 1938

B₁, pigeon weight and rat growth factor

B₆, rat dermatitis factor isolated and identified in 1938 (pyridoxin)

B₂ (G), riboflavin identified in 1933 and synthesized in 1935

Nicotinic acid, antiblacktongue and pellagra factor identified in 1911, rediscovered in 1937

Unknown factors

Thermolabile

B₃, pigeon weight and antigizzard erosion factor identified in 1928

B₄, rat antiparalysis factor identified in 1929

Factor W, growth factor identified in 1936

B₁, thiamin chloride isolated in 1926, synthesized in 1936

Lecture given before the Section of Internal Medicine and Pathology of the Queens County Medical Society on March 7, 1939

From the Medical Service and Nutrition Clinic of the Queens General Hospital. Dr. A. Victor, director.

* Since this paper was submitted for publication a number of reports have appeared in the literature indicating that vitamin B₅ is of importance in human nutrition.

Spies, Bean, and Ashe [Note on the Use of Vitamin B₅ in Human Nutrition J. A. M. A. 112: 23 (June 10) 1939] described a syndrome characterized by extreme nervousness, insomnia, irritability, abdominal pain, weakness, and difficulty in walking. This disappeared on injecting 50 mg. of vitamin B₅ intravenously.

Antopol and Schotland [The Use of Vitamin B₅ in Pseudohypertrophic Muscular Dystrophy J. A. M. A. 114: 12 (Mar. 23) 1940] report favorable results from the use of vitamin B₅ in pseudohypertrophic muscular dystrophy.

Jolliffe [quoted by Spies, T. D., Hightower, D. P., and Hubbard, L. N. Some Recent Advances in Vitamin Therapy J. A. M. A. 115: 4 (July 27) 1940] employed vitamin B₅ in certain cases of paralysis agitans. These reports are very promising and suggest that vitamin B₅ is a clinically useful substance.

Riboflavin

The first of the substances to be isolated was riboflavin. It was recovered from milk in the form of pure crystals. In 1935 its formula was established and its synthesis was accomplished. Riboflavin prevents cataract formation in rats and promotes their growth. It also prevents dermatitis in turkeys. There is evidence that it forms the coenzyme of a yellow respiratory enzyme that functions as a dehydrogenase. The exact clinical function of riboflavin is not known. However, in December, 1938, Sebrell and Butler² reported that riboflavin is important in human nutrition. Vilter, Vilter, and Spies³ reported that 4 cases of pellagra, whom they kept on a pellagra-producing diet supplemented by nicotinic acid and thiamin chloride, began to lose weight and developed a dermatitis, but the administration of small doses of riboflavin resulted in well-being and in the improvement of the cutaneous lesions. Jolliffe⁴ feels that riboflavin deficiency may account for the sudden death of certain beriberi patients. Sydenstricker, Geeshin, Templeton, and Weaver⁵ confirmed the work of Sebrell and Butler and described 5 human cases of riboflavin deficiency. These patients showed a dermatitis at the corners of the mouth (or cheilitis) and an atypical dermatitis of the hands. These authors administered, parenterally, doses as high as 60 mg. of riboflavin daily. However, further work will be needed to determine the exact role of riboflavin in human nutrition.

Nicotinic Acid

Nicotinic acid was isolated from rice polishings and yeast in 1911 by Funk during his studies on beriberi. However, when he found it did not cure beriberi, he paid no further attention to it. Elvehjem,⁶ during his studies on blacktongue in dogs, isolated nicotinic acid from liver extract and found that it was useful in curing pellagra. Nicotinic acid derives its name from the fact that one way of preparing it is by oxidation of nicotine. However, nicotinic acid is not poisonous and is to be considered a vitamin.⁷

Occurrence in Foods—There is evidence that nicotinic acid is present in a number of foods, chiefly, liver, yeast, and lean meat.

The amounts are small—yeast contains 0.018 per cent

Physiologic Significance—There is evidence that nicotinic acid is a constituent of the respiratory enzyme cozymase. Vilter, Vilter, and Spies³ found that in the blood of persons suffering from pellagra cozymase is present in insufficient quantities to support the growth of the *Bacillus influenzae*. The blood of normal individuals and of pellagra patients receiving nicotinic acid or its amide has the ability to support the growth of *B. influenzae*, but nicotinic acid as such, when added to a transplant of *B. influenzae*, will not support its growth. Hence, these authors conclude that nicotinic acid is utilized in the human body as a component of an enzyme group.

Clinical Use—Nicotinic acid is used both for the prevention of pellagra as well as the treatment for it. Fouts⁸ also Spies^{9,10} report the use of nicotinic acid in doses from 100 to 1,000 mg for the prevention and treatment of pellagra. They found the substance effective in a large group of persons with pellagra. They point out that nicotinic acid will relieve only symptoms due to the deficiency of nicotinic acid alone. Polyneuritis or the other deficiency states that complicate pellagra require additional supplements to the diet. Spies^{9,10,11} and also Schmidt and Sydenstricker¹² assert that nicotinic acid alone cannot be expected to cure pellagra permanently, but a 4,000-calorie high vitamin and high protein diet is necessary for the maintenance of the cure. Nicotinic acid may be employed in any case of suspected pellagra. Stomatitis and glossitis^{13,14} are indications for the use of nicotinic acid. It should be given after food in doses of 100 mg every two hours to tolerance. It is soluble, can be taken in water or any other liquid, and can be injected parenterally. The symptoms of intolerance are flushing of the skin, nausea, and occasional vomiting¹⁵. Thus far, no serious toxic symptoms have been encountered. The flushing of the skin is temporary. Individuals vary in their tolerance of nicotinic acid. However, it is best to give large doses up to 1,000 mg in divided doses on the first day and then give as much of the drug as the patient will tolerate on the second day. The dose is reduced to a maintenance level, the guide being the tolerance of the patient. The author administered 500 mg to patients for several weeks without untoward symptoms.

A few interesting observations were made during the work with nicotinic acid (1)

Fig 1 Diagram Illustrating Constituents of the Vitamin B Complex.

The patient receiving it develops a sense of well-being (2) The sensorium clears (3) The dermatitis lightens (4) The stomatitis and glossitis disappear (5) The appetite improves (6) The desire for smoking in heavy smokers seems to be lessened (7) The response of a patient to nicotinic acid may be of prognostic significance, for cases where nicotinic acid is of transient or no effect as a rule do not recover.

Thiamin Chloride

Thiamin chloride or vitamin B₁ was isolated by Jansen and Donath in 1926. R. R. Williams in 1936 synthesized the vitamin. It is a crystalline powder, is soluble in water, and has a yeasty taste.

Occurrence in Foods—Thiamin chloride is present in most animal and plant tissues.¹ For the most part it is contained in minute quantities about 1/2,000,000. On the whole, this vitamin is present in submarginal quantities "so that nature has a struggle to make and maintain adequate supplies of the vitamin to keep life moving forward at an optimal pace."¹ The best food sources of thiamin chloride are the whole seeds of plants and cereals, yeast, and certain animal tissues such as pork, liver, heart, and kidney. A well-balanced daily diet contains about 1 mg of thiamin chloride.¹⁶ However, most American diets fall below the above figure in thiamin content.¹⁷

Physiologic Significance—Thiamin chloride

is essential for the metabolism of all cells. It is intimately connected with the carbohydrate metabolism. Thiamin chloride is a constituent of several enzyme systems concerned with the oxidation of carbohydrate metabolites, such as pyruvic and lactic acids, etc., to carbon dioxide and water.^{1,18} There is evidence that there is an accumulation of pyruvic acid and related substances when a thiamin chloride deficiency exists.¹⁹ The more physiologically active a cell is, the more need it has for thiamin chloride.¹ This may explain why a deficiency of thiamin so profoundly affects the tissues of the nervous and circulatory systems. Thiamin is stored in the tissues especially in liver, kidney, heart, and brain. On deficient diets the amounts stored decline rapidly at first, but the last minimal amounts are retained quite persistently.¹ The brain conserves its supply even at the expense of other tissues.¹

Clinical Uses of Thiamin Chloride—Williams and Spies¹ state that thiamin is not a specific substance for any one disease but is nevertheless of help in numerous affections. Thus they explain by the universality of the need of thiamin chloride on the part of all the tissues. The classic use of thiamin chloride is in beriberi. It is effective in the dry or polyneuritic form, as well as the wet or circulatory form where edema is the predominating factor. Polyneuritis in any form is probably an indication for the use of thiamin chloride. Jolliffe and his coworkers^{20,21} proved that alcoholic polyneuritis is similar to beriberi as it occurs in the Orient and that it responds to treatment with thiamin chloride. Thiamin chloride may be administered orally, subcutaneously, intramuscularly, and intravenously. Williams and Spies have given 500 mg daily for a month to normal people without ill effects.¹ The author has employed doses as high as 100 mg intravenously for a week without ill effects. There is a wide range between the therapeutic and toxic dose, so that for ordinary purposes thiamin chloride can be regarded as nontoxic. Recently, however, herpes zoster²² was reported as a complication following the administration of thiamin chloride.

When definite clinical manifestations such as polyneuritis exist, it is the consensus among the workers in this field that the doses should be high. Injections of less than 20 mg daily are probably inadequate to produce a prompt result, and doses much higher than this may be needed. When the patient is very ill or when there is any doubt about the ab-

sorptive capacity of the gastrointestinal tract, the vitamin must be administered parenterally. Intravenous injections are apparently harmless and are quite efficacious. Since there are at present no simple clinical tests to judge the sufficiency of thiamin chloride therapy, one must guide himself by the clinical results and gauge the dosage accordingly.

When should thiamin chloride be employed? Aside from beriberi when the indication is clear, thiamin chloride may be employed to advantage in any condition where a dietary deficiency exists, in cases with heightened metabolism such as fever, hyperthyroidism, pneumonia, etc. Diabetes offers a fruitful experimental field for the employment of thiamin chloride. If in a routine examination the patient exhibits such signs as marked muscle tenderness, especially calf tenderness, plantar hyperalgesia with hyperactive, or absent deep reflexes, thiamin chloride may be of use. There is no clinical contraindication to its use. There is, however, an important drawback to its indiscriminate employment—it is expensive. Therefore, thiamin chloride should be used judiciously so as to conserve the patient's resources but unhesitatingly and in sufficient amounts when indicated.

Thiamin chloride will not help any other deficiency state. Hence, the patient must be searched for evidences of deficiencies of other nutrients, and, if present, these should be treated. Again diet is the mainstay in treating thiamin chloride deficiency as it is in the therapy of any deficiency state. The following cases are cited as illustrations.

Case Reports

Case 1—C. R., white man, aged 60, was operated on for a hypertrophied prostate. He was discharged with an abdominal sinus through which urine came out. When he left the hospital, he lived in a furnished room, and then for some time he was homeless so that he was compelled to sleep in the park. When he was readmitted to the hospital, about a month after he left, he appeared chronically ill. He was mentally depressed and retarded and somewhat disoriented. He ate poorly. His tongue was dry. The skin of the dorsum of the hands to above the wrists was bilaterally and symmetrically excoriated, thickened, and reddened. The diagnosis of pellagra complicating a persisting urinary sinus was made. He was given 500 mg of nicotinic acid and a 4,000-calorie, high protein diet. Within forty-eight hours he became rational and cheerful. His appetite improved so that he consumed all the food given to him. The skin gradually cleared and he was discharged at the end of two months. His urinary sinus still persisted, but his weight increased from 131 to

143½ pounds His mentality was lucid, and his skin was normal

Case 2—M Q, white man, aged 43, was admitted to the hospital with a history of rheumatic heart disease of sixteen years' duration. He had been in bed for 1½ years prior to admission to the hospital He had been treated at home with digitalis, mercupurin, and intravenous glucose He had received considerable amounts of pantopon, and he was sensitive to morphine His wife related that during his illness he received about 1,000 hypodermic injections of one kind or another He hardly consumed any food at home There was no alcoholic history On admission he appeared very ill He was entirely disoriented and had visual and temporal hallucinations, delusions, and confabulations There was edema of the feet and legs and a right hydrothorax was present The heart was enlarged Mitral stenosis, mitral insufficiency, aortic stenosis, and aortic insufficiency were present A bilateral peripheral neuritis involving the lower extremities with a bilateral foot drop was noted The knee and ankle jerks were absent and there was marked muscle tenderness The diagnosis was rheumatic heart disease complicated by a thiamin chloride deficiency Fifty milligrams of thiamin chloride was given the first day, intravenously Within twenty-four hours he was mentally clear and the edema of the legs and feet was much less This dose was continued for five days Twenty-five milligrams was given for two days and 10 mg was given for about ten days, and then this dose was reduced to 5 mg daily He improved considerably, the edema disappeared, the sensorium cleared, the hydrothorax lessened some, and he ate better and became stronger The foot drop also improved to such an extent that for the first time in 1½ years he was permitted to leave the bed He even stood on his feet About one week before his death he developed a sudden toothache of such severity that one of the interns had to administer morphine to him Shortly thereafter, he became drowsy, developed heart failure, coughed up some rusty material, and died after several days Postmortem showed an enlarged heart, an old lung infarct, and mitral and aortic disease

This case is mentioned here because of the temporary response of the patient to thiamin chloride despite the gravity of the underlying illness

Case 3—J G, white man, aged 23, was admitted to the hospital because of an extensive tuberculosis for which a thoracoplasty was done in two stages When first seen at the hospital, he was extremely emaciated The tongue and buccal mucous membrane presented an extensive grayish white patchy slough with intervening areas of deep red Because of this he was practically unable to swallow anything, since swallowing was very painful There was considerable muscular atrophy The muscles were also

tender There was marked plantar hyperesthesia, and he was very irritable The thoracoplasty wound was open and discharging and he had a bed sore on his back The sputum was positive for *Bacillus tuberculosis* The following doses of nicotinic acid were given on successive days 1,000, 800, 600, 300, 400, 200, 100, 100, 50, and 50 mg The latter dose was continued for two weeks and then stopped because he developed symptoms of intolerance About two weeks later the nicotinic acid was resumed in 50-mg doses and was given daily for almost two months On the second day, twenty-four hours after the administration of nicotinic acid, there was an improvement The patient was now able to take orange juice and other fluid nourishment, and within a few days he was able to take solid food The mouth lesions disappeared after a period In addition to nicotinic acid he received two doses of thiamin chloride, 25 mg intramuscularly and 75 mg by mouth Then Brewer's yeast was given for eight days in doses of ½ to 2 ounces, but the patient refused to take the yeast He was also given at least 1 pint of citrus juices daily and 30 drops of percomorph oil daily A high protein and high vitamin diet was given His average intake of calories was from 2,000 to 3,200 a day After a stormy course of several months, he became ambulatory, gained fifteen pounds in weight, and was well enough to be discharged to a tuberculosis hospital

Summary

Vitamin B is a generic term that includes a number of constituents Nicotinic acid,* thiamin chloride,* riboflavin,* and probably pyridoxin are of importance in human nutrition

Nicotinic acid, thiamin chloride, and riboflavin are components of enzyme systems that are of great importance in tissue metabolism Consequently, a deficiency of these substances produces profound changes in the living organism

Nicotinic acid and thiamin chloride and probably riboflavin when used in indicated cases and in proper doses are therapeutically effective and important substances

STORED BLOOD FOR TRANSFUSION

From the Emergency Blood Transfusion Service of Edinburgh and southeast Scotland C P Stewart reports in the *Edinburgh Medical Journal* studies on the use of stored blood in 427 transfusions. He points out, as summarized in a London letter to the *J. A. M. A.*, that for certain purposes the therapeutic value of blood must steadily decrease during storage. Thus the disappearance of leukocytes, reported by several observers, means that blood should not have been more than two days in storage if one of the objects for which it is used is to supply leukocytes.

But if the object is to supply fluid and oxygen carrying power there seems no reason, on the basis of laboratory examinations of stored blood, why it should not be used after as much as thirty days of storage. However, clinical trial is essential and it is extremely difficult to judge the relative value of stored and fresh blood. In surgical cases the therapeutic results appear to be independent of the age of the blood. But in such conditions as leukemia, various types of anemia, septicemia, and toxemia, blood is now used which has been in storage as short a time as possible, and the results have greatly improved.

All the transfusions in this series were done with blood which had been withdrawn into 3.8 per cent sodium citrate solution with a final concentration of 0.38 per cent citrate, stored at a temperature of from 2 to 5 C. In most cases it had been filtered after being stored for forty-eight hours.

In the 427 cases there were 58 reactions, of which 9 were fatal, 16 were only febrile, 7 were transient jaundice, and 26 were rigors. The total percentage of reactions was 13.6, which in the 259 cases of the series of transfusions done in the present year was reduced to 10.4 with only one death. This reduction of incidence of reactions

coincided with the use of blood of lower average "age."

The deaths appeared to be due to acute cardiac failure following injection of fluid and not to any factors which could be attributed to the use of stored blood, though some followed a transfusion reaction (rigor). One writer, V. H. Riddell, states in his book on blood transfusion that deaths from circulatory failure after transfusion with fresh blood are much commoner than is generally supposed, although they are rarely reported.

Stewart investigated the relation between the incidence of reactions and the time of storage by classifying the cases into five-day periods. Under twenty-four hours the percentage was 12.5, from one to five days 14, from six to ten days 5.2, from eleven to fifteen days 15.6, from sixteen to twenty days 22, from twenty-one to twenty-five days 15, and from twenty-five to thirty days 26.

When the cases were further analyzed according to the storage time in days from none to fourteen, it was found that blood stored from four to ten days was safer than blood stored for a shorter time or even than fresh blood. The reason for this was not clear, but it might be related to the disappearance of leukocytes during the first few days of storage. The increased reaction incidence after the tenth day may be associated with the disruption of erythrocytes.

It appears that stored blood is no more likely to produce reactions during the first fortnight than is fresh blood. But after that period the likelihood of reaction is increased. Therefore, while it is possible to use in cases of emergency blood stored longer than a fortnight, it seems better in ordinary cases to regard this period as the maximum.

MISSISSIPPI VALLEY MEDICAL SOCIETY 1941 ESSAY CONTEST

The Mississippi Valley Medical Society offers annually a cash prize of \$100, a gold medal, and a certificate of award for the best unpublished essay on any subject of general medical interest (including medical economics) and practical value to the general practitioner of medicine. Certificates of merit may also be granted to the physicians whose essays are rated second and third best. Contestants must be members of the American Medical Association who are residents of the United States. The winner will be invited to present his contribution before the next annual meeting of the Mississippi Valley Medical Society at Cedar Rapids, Iowa, October 1, 2, 3,

1941, the Society reserving the exclusive right to first publish the essay in its official publication—the *Mississippi Valley Medical Journal* (incorporating the *Radiologic Review*). All contributions shall not exceed 5,000 words, be typewritten in English in manuscript form, submitted in five copies, and must be received not later than May 1, 1941. The winning essay of the 1940 contest appears in the January, 1941, issue of the *Mississippi Valley Medical Journal* (Quincy, Ill.). Further details may be secured from

HAROLD SWANBERG, M.D., Secretary
Mississippi Valley Medical Society
209-224 W. C. U. Building, Quincy, Ill.

DACRYOCYSTITIS OF THE NEWBORN

HARRY V JUDGE, M D , Albany, New York

A PERUSAL of the textbooks dealing with ophthalmology reveals that the subject we are considering is listed under the heading "congenital dacryocystitis." With such a terminology we are to assume that a child so affected was born with an inflammation of the lacrimal sac. Our knowledge of the subject contradicts this assumption.

The primary pathology which gives rise to the condition is embryologic in origin. It is due to an incomplete or delayed canalization of the nasolacrimal duct. Associated with these defects may be the presence of a collection of cells at the lower end of the lacrimal canal which have become separated from the walls of the canal during their later stages of development and have come to lie at the lower end of the duct, either just within or without the opening of the canal. In the former situation they are probably being held back by the presence of a small band of tissue in an imperforate opening in the nasal mucosa where canalization was incomplete, or in the latter situation, having been extruded from the patent duct, they have come to lodge about its opening. The presence of these cells may act further as a contributing factor to obstruction of the canal by producing a turgescence of the nasal mucosa in their immediate neighborhood, thus further impeding normal drainage through the canal. It is to the latter factor that reference will be made again when another method of treatment will be suggested for the relief of this condition.

According to Zentmayer,^{1,2} other etiologic factors are considered (1) faulty development of the cartilages, (2) partial occlusion by pressure from the inferior turbinate, and (3) stenosis from pressure exerted on the bones of the face during instrumental labor.

Irgeshimer is the author of the statement that many of these cases are due to hereditary syphilis.

In view of the numerous permanent cures which are reported as a result of spontaneous opening or other relief measures, the incidence of these more commonly unaccepted causes must be relatively small.

It is difficult or impossible at the start to know with which factor we are dealing. It is only with a progressive series of diagnostic and therapeutic procedures that we are able

then to assume with which type we have been confronted. This approach will be described.

From the clinical point of view two types may be assumed to occur.

(1) Simple represented by a low-grade infection of the sac. Some of these are believed to be cured spontaneously when the mechanical obstruction at the lower end of the duct is relieved by nature itself. In this same class may be considered those cases that are relieved rather promptly by expression of the sac supplemented by irrigation and the installation of an antiseptic.

(2) This is a more difficult group that fails to respond to the usual simpler approaches and that ordinarily responds promptly to the introduction of a probe. These must be considered cases of imperforate openings. With the mechanical factor more evident in this group and with patency of the duct not established, complications are more likely—the development of an acute dacryocystitis or a transition of the case into one of chronic dacryocystitis.

Attention is first drawn to the eyes several days after birth when a small amount of lacrimation will be observed. There may be a small collection of tears in the lacus lacrimalis as the lids are separated. Not infrequently we observe a small amount of mucopurulent material matting the cilia together. There is a conspicuous absence of any inflammatory signs of the bulbar or palpebral conjunctiva. In the majority of cases these signs are so slight that a diagnosis of the real condition might be overlooked unless, as a routine procedure in the examination of the catarrhal eye of the newborn, pressure be made over the lacrimal sac. In cases in which regurgitation is not elicited at the first examination, it is wise to repeat it. In other cases there are slight inflammatory signs of the bulbar and palpebral conjunctiva, and in some there is observed an acute inflammation of the sac with redness and swelling of the region. The natural tendency of the conjunctival sac is to drain toward the puncta and frequently leads to the collection of purulent material at the inner canthus of the eye, and, unless this is removed prior to the time pressure is made over the sac, it may be difficult to observe whether the pus had been regurgitated from the puncta or had collected at the inner canthus over the plica. The task is enhanced

Read at the Annual Meeting of the Medical Society of the State of New York, Syracuse, April 26, 1939.

by the smallness of the structures, lids, and puncta, and the act of manipulating them into proper position to show eversion of these parts is sometimes trying

To facilitate one's observation, the use of the Berger loupe is urged. The head of the child should be steadied by an assistant. A wooden applicator is wound with a small amount of cotton so arranged that a small bulbous end is developed. After the eyelids have been wiped dry with a small amount of cotton, they are separated by means of the thumb and index finger of the left hand so as to expose each punctum. At this point pressure is made over the sac in the region corresponding to the internal palpebral ligament, and regurgitation through the puncta is looked for.

One will be greatly surprised at the wide variance in the amount of material that will be expressed. In some cases it will be extremely scant, just a drop or two, while in others a surprisingly large amount will be recovered. It is in this latter group that Craigler described his forceful expression of the sac. In the earliest days the secretion is of a clear, watery, or mucoid character, but after a short interval, when secondarily infected, the secretion takes on a mucopurulent or purulent character. It is then that we may see cases presenting a slight or a moderate degree of conjunctivitis or a slight swelling or erythema of the skin in the region of the lacrimal sac. It is the latter group, unless relieved, that may lead to the unusual complication of lacrimal abscess. Bilateral involvement may occur but is not common.

Differential diagnosis is limited to three other conditions

(1) Silver nitrate reaction. This is usually accompanied by an active reaction of the bulbar and palpebral conjunctiva as expressed by slight or moderate congestion. The stained secretions are negative for gonococci, and the signs usually disappear in several days.

(2) Gonorrheal infection. Here the prompt swelling of the lids is marked with a profuse, creamy, purulent discharge and the finding of the organisms in the smear.

(3) Inclusion blennorrhea. This is a mild inflammation of the eye of the newborn, appearing several days after birth, accompanied by only slight swelling of the lids. The presence of inclusion bodies may be detected with a Giemsa or Wright stain of the secretion.

The above conditions are likely to be bilat-

eral and regurgitation of the sac contents is absent in all.

It must be recalled that many of these cases will cure themselves without any treatment. Such is the experience recorded by obstetricians. These indicate a spontaneous opening of the lacrimal canals or the clearance of epithelial debris from the nose through the act of sneezing or aspiration.

In the approach of the other group of cases the following procedure is recommended.

When the presence of dacryocystitis is established, a small nasal applicator is wound tightly with a minimum of cotton—just enough to cover the metal probe. This is advanced along the floor of the nose on the affected side, and in the act of withdrawal it is made to hug under the lower surface of the inferior turbinate bone. One will frequently be surprised to find on withdrawal of the applicator a collection of mucus, epithelial cells, and debris. The mass may be soft or somewhat inspissated. It is frequently accompanied by a sticky, tenacious secretion. If one is fortunate enough to meet such findings, no further treatment is applied, and the mother is directed to return with the infant on the following day. If this offending debris had been the causative agent for the improper drainage through the canal, one may be agreeably surprised to find the sac dry on the following day, and, if not entirely dry, only the slightest amount of mucous material may still be expressed. If the latter is present, it is assumed that the failure of immediate response is due to the presence of a turgescence of the mucous membrane, on the incidence of its disappearance the drainage is established, and on the second or third day no regurgitation will be apparent.

In the literature reviewed I have seen no reference to such an approach in dealing with dacryocystitis of the newborn. A somewhat analogous procedure was noted by Zentmayer¹ in which he remarks "A successful method, not recommended by any writer, was witnessed by Capez, according to Van Duyse (Ann Soc de Med de Gaud, 1892, LXXI, Pages 11 to 19). This author saw a lachrymal tumor rapidly cured by the nurse applying mouth suction to the nose of the infant." In lieu of such a procedure, it must be assumed that such a cure was effective in a case where epithelial cells and debris were the offending agents. An imperforate canal could not be opened by such a procedure.

The second approach, expression, can be carried out by one of two methods. In the

first, repeated expressions of the lacrimal sac are made several times a day, followed by boric acid irrigations and the installation of an antiseptic. A 1 per cent aqueous ethylhydrocuprein hydrochloride solution has afforded excellent results.

Creigler has described a method for expressing the contents of the lacrimal sac downward in an effort to open the nasolacrimal duct by hydrostatic pressure. Occasionally this happens unintentionally in the act of examining the sac for regurgitation. Creigler's method is described in his own words:

"Method of Procedure"

"1 The tear sac is allowed to become fully distended. We caution the mother not to wipe the eye or in any way to press on the sac before coming to the clinic or office. She is given a 25 per cent solution of protargin mald (argyrol) or other antiseptic eye lotion, to be dropped into the culdesac three times a day, to protect the eyeball from infection.

"2 The infant's head is held between the surgeon's knees in a manner similar to the method in vogue of inspecting the eyeball. Assuming that it is the right sac that is affected, he places his right thumb over the sac in a way to shut off the return flow through the puncta. This is done by holding the thumb sidewise, with the thumb nail outward and forming an acute angle with the plane of the iris. The edge of the thumb is now pressed downward over the puncta, compressing it against the rim of the orbit, with this point of pressure maintained, the thumb is rotated to the right, at the same time pressing downward, abruptly over the sac. The fluid, now being compressed by the thumb, transmits the pressure to the walls of the sac, which must give way at its weakest point, which happens to be the site of the nasal opening. Repeated cures, after one manipulation of this sort, and no failures so far, extending over a period of seven years, convince me that the probe should never be resorted to except as a last resort.

"The salient points to be remembered are

"(1) Pressure must be made over the sac only when it is distended.

"(2) Care should be taken that the thumb is applied in such a way as to prevent regurgitation into the conjunctival sac.

"(3) Sudden pressure over the sac causes the retained fluid to burst through the persistent fetal membrane which separates the mucous lining of the nose from that of the nasal duct."

After two to three weeks of conscientious expression as advised under the first group of this phase of treatment, the use of the probe should be advised. The probing of the duct of the newborn is usually not attended with difficulty. While the maneuver can be ac-

complished without the aid of an anesthetic, preference is for a very light ether anesthesia sufficient to secure quiet of the head, particularly in babies over 6 to 8 weeks of age. The use of the Berger loupe is urged again to accentuate the anatomic markings. Having evacuated the contents of the sac, the conjunctiva is flushed with boric acid solution. To enlarge the lower punctum a Wilder's long taper punctum dilator is introduced gently for about 2 to 3 mm. This should not be carried beyond this point, otherwise, with the increasing taper of the instrument, the sphincter muscle surrounding the punctal opening might be ruptured and the capillary action of this structure be destroyed. For the same reason slitting of the canaliculus is deprecated. A No. 1 Bowman probe is advocated. After introduction into the punctum, the probe is carried inward on a horizontal plane to meet the nasal bone. At this latter point the instrument is steadied by gentle pressure, turned to the vertical, and passed downward in the canal, its course prescribed by a line drawn from the inner canthus to the corresponding nasolabial fold. It must be remembered that its course is short, 5 to 6 mm, representing the distance from the lacrimal fossa to the floor of the nose. Ordinarily the probe is passed with ease and is soon felt to meet resistance on the floor of the nose. To make sure that the probe has reached the nasal cavity, a second probe can be introduced along the floor of the nose and made to course along the outer wall. If the first probe has reached the floor, a metallic click can be felt and sometimes heard when the second probe engages the first. In addition, a movement of the upper end of the first probe is apparent when agitated from below. In other instances, the probe can occasionally be seen with the aid of a nasal mirror and a small nasal speculum.

No complete statistics as to its incidence are available. Zeigler saw 2 cases in twenty years of practice. In the combined private practice and the Rostock clinic practice of Professor Peter only 17 cases were observed between 1901 and 1908. In the course of three and one-half years, 15 cases were treated at the women's clinic in Dortmund. Robert A. Campbell reports 5 cases observed over a period of twelve years. I have observed 26 cases in the course of eleven years. This higher incidence may be explained by my association with a maternity hospital and with the obstetric department of a general hospital.

The age of the infant at the time of the first visit in the practice of others was a variable

factor, usually from 6 to 14 weeks. In my practice the average age was 7 weeks, although they have been seen as early as 1 to 2 weeks. Four cases with a diagnosis of chronic dacryocystitis were observed in the first years of life as a result of neglect or improper treatment. All 4 gave histories involving the lacrimal apparatus shortly postpartum. Two of these were relieved by extirpation of the sac. Treatment was deferred in the other 2 cases.

A gradual approach in the form of treatment is recommended, advancing from the simplest to the more radical. By this method probing may be avoided in approximately 50 per cent of the cases, 25 per cent responding to the nasal approach and the other 25 per cent by expression. The promptest relief is obtained by probing, although this may occasionally have to be repeated in order to effect a cure. Those responding to the method advocated by Creigler and the others who were relieved by the nasal approach were cured in from two to three days.

Cure by repeated expression was slower, averaging about eleven days, but in some instances cure was delayed slightly beyond this time.

Discussion

Dr Mortimer A Lasky, *Brooklyn*—Dr Judge is to be congratulated for his excellent presentation of the etiology and methods of treatment for this not uncommon ailment. This condition has been sadly neglected in most of the texts and in scientific meetings. It is very easy to minimize such cases, and, as we know, many cases of chronic dacryocystitis with all its accompanying suffering, inconveniences, and complications result from careless neglect or inadequate treatment. With such a simple procedure as Dr Judge describes, it should be unnecessary for the great majority of these conditions to fail being cured when still in their early stages.

The technic is not complicated and is apparently very successful. The mere removal of a mass of mucus and cellular debris from the nasal end of the nasolacrimal duct serves to establish drainage and obviate any further treatment. It is a means of treatment that does not require the services of an ophthalmologist. All general

practitioners and obstetricians should be made cognizant of this procedure so that they will apply it as soon as a watery eye is discovered. Thus, there would be no tendency to procrastinate and wait for nature to repair a defect that might be more serious than realized. If the condition is not corrected by this early treatment, the practitioner should certainly become concerned enough to seek the advice of an ophthalmologist and not wait for an inflammation to supervene.

Dr Judge objects to the commonly used term "congenital dacryocystitis," which implies that the infant so affected was born with an inflammation of the lacrimal sac. This is a valid objection for the great majority of these cases. However, I have personally seen a newborn who had an acute dacryocystitis at birth. The region of the sac was red and distended and the eye was watery. The tumor mass was incised on the second day and a thick creamy pus was obtained. It proved to be a staphylococcal infection which cleared up very promptly after a bacteriophage solution was injected into the sac through the skin incision, resulting in a sudden flow of mucus and pus out of the nose. I feel that this was merely a mechanical cure.

I wish to thank Dr Judge for giving us this new method which is certainly a very useful adjunct to our therapeutic armamentarium and which will probably result in many earlier cures and make unnecessary the too frequent reliance on probing or irrigations with their often unavoidable exposure of an infant to the dangers of a general anesthetic.

Dr James I. Farley, *Utica, New York*—It has been a pleasure to have read Dr Judge's paper on "Dacryocystitis of the Newborn." He has covered the subject quite completely. He does make this statement, "The incidence of these more commonly unaccepted causes must be relatively small," and I would like to ask him to explain it more fully.

I have had no experience in the treatment he describes in which he uses a nasal applicator, wound tightly with cotton, to clean out the area beneath the inferior turbinate bone. During the past seven years I have seen 8 infants on whom I have made a diagnosis of dacryocystitis of the newborn. Five of these responded to expression, and 3 had to be probed before showing a cure. With all patients the mother was advised to douche the eye at least morning and night with boric acid solution and to instill a drop of 2 per cent mercurochrome following the douching. At the time of each feeding, I had the mother instill a drop of 1/4 per cent of zinc sulfate solution. Before the douching she was instructed to exert pressure on the lacrimal sac, pressing backward, inward, and slightly downward, and she was told the reason why. If any matter regurgitated from the sac, it was removed by the douching. If after 6 months of age there was still a blockage,

probing was resorted to. In those cases where probing has not been necessary, a cure has been obtained within two or three weeks of treatment. Ether anesthesia was used in the 3 patients in which the probe was passed.

Dr. Jason L. Wiley, *Auburn, New York*—I have little to add to Dr. Judge's excellent presentation of this subject. I have seen 10 cases in a practice of twenty years. Two of these were cured by expression and 8 by the probe. I have not been in the habit of expressing as long as Dr. Judge advocates. I wonder if this is entirely devoid of danger. With proper care, probing seems to me almost without danger. May I ask Dr. Judge if he has seen any definite permanent damage from the use of the probe? I question the value of any antiseptic three times a day in a conjunctival sac that is bathed with pus twenty-four hours a day.

Dr. Judge says nothing about cases of a solid bony obstruction. While I have never seen this condition, Dr. Benedict, of Rochester, has reported it and says he believes it is usually due to congenital syphilis. In 1 case I was unable to pass a probe through the lower canaliculus but met with no difficulty through the upper canaliculus, and the condition was as satisfactorily cured as any of my other cases. I have not seen a bilateral case nor have I seen an acute abscess in these patients.

I am grateful to Dr. Judge for his paper and especially for the suggestion that a goodly percentage of these cases can be cured by swabbing under the lower turbinate of the affected site. This is new to me, and I shall try it in all cases in the future. I think a suction apparatus with a small tip might be more efficient for this purpose.

THE N. Y. ACADEMY ELECTS OFFICERS

The election of the following officers of The New York Academy of Medicine took place on December 5, 1940: president for a term of two years, Malcolm Goodridge, M.D., vice-president for a term of three years, Henry Cave, M.D., two trustees for a term of five years, George Baehr, M.D., and Arthur F. Chace, M.D., three

members of committee on library for a term of three years, Alfred E. Cohn, M.D., Howard R. Craig, M.D., and Jerome P. Webster, M.D., four members of committee on admission for a term of three years, J. William Hinton, M.D., John E. Scarff, M.D., William E. Studdiford, M.D., and Edward Tolstoi, M.D.

THE INHIBITING ACTION OF TESTOSTERONE PROPIONATE IN POSTPARTUM LACTATION

ALFRED M. HELLMAN, M D , F A C S , and LEONARD F. CIMER, M D , New York City

THE male sex hormone, testosterone propionate, has been used to some extent and with varying results in the treatment of certain disorders of the mammary gland in both male and female

Wernicke¹¹ reported the use of this hormone in 4 cases (3 with atrophied left testicle) having unilateral gynecomastia. Testosterone propionate was employed in doses of from 2½ mg twice weekly to 25 mg three times weekly according to response. Although the normal case in his series was unresponsive, of the 3 with atrophied testicle, 2 were favorably influenced. Hoffman⁶ also employed testosterone in the treatment of males with breast hypertrophy. Twenty-eight patients (ages 11 to 73) were injected with 5 to 25 mg twice a week with resultant regression in size of the mass in 14 and a degree of regression exceeding 75 per cent occurring in 9 cases. The elapsed time before complete regression occurred varied from two to five months, and the number of injections averaged twenty-eight. It was not unusual to note a regression of 50 per cent during the first four weeks of treatment. Bender² treated 12 cases of premenstrual mastopathy with testosterone propionate over a period of six months according to the following schedule: two to three days previous to the anticipated onset of breast symptoms each patient received four injections of 5 mg on alternate days, the date for initiating therapy being selected so that treatment would be discontinued two days prior to menstruation. Four cases in his series were completely and permanently relieved of their mastopathy, 6 were greatly benefited, and 2 were unresponsive. Desmarest and Capitain⁴ also administered testosterone propionate to women with premenstrual mastopathy and obtained uniformly good results. Irregular and painful menstruation concomitant with the mastopathy was relieved and cystic mammary swelling diminished. They noted that the normal menstrual cycle was not affected by therapeutic doses. Spence⁹ employed testosterone propionate in the treatment of 16 cases of masti-

tis, using doses of 25, 50, and 100 mg usually twice a week for several months. Fourteen of these cases were relieved of pain, nodules disappeared in 3 cases and in 5 cases there was a reduction in size of nodules.

Postpartum engorgement of the mammary gland is a common disorder and one frequently accompanied by considerable discomfort. In this condition, which appears from one to four days after delivery, the breasts are heavy, swollen, painful, and tender, and the overlying skin presents a reddish blue, mottled appearance. The nipples often are retracted to such a degree that the very means designed by nature to bring relief—namely, natural withdrawal of the milk secretion—becomes impossible. The usual measures for combating this disorder are elevation of the breasts, application of cold (occasionally heat) and a tightly fitting binder, restriction of fluids, low caloric diet, saline cathartics, and the administration of sedative drugs. Despite these active ministrations, the discomfort experienced during the first few days postpartum is often recalled with greater clarity than that suffered during labor itself. Although the cause of breast engorgement in these cases is largely due to venous stasis and interference with the lymphatic circulation, nevertheless a definite amount of milk secretion is present and adds measurably to the extent of the discomfort. Under stimulation of the lactogenic hormone elaborated by the cells of the anterior pituitary gland, swelling of the acinar cells of the breast takes place, the lymphatics become engorged, and the individual milk ducts become palpable. If nursing is possible or if withdrawal of the breast contents is affected by other means, the gland cells are split into globules of fat, and milk is elaborated from the neighboring lymphatics. Though the entire process is physiologic, it is frequently carried to an unpleasant extreme, especially in primiparas. Abarbanel,¹ in a series of 50 patients with severe and painful engorgement, was able to effect practically complete relief in 92 per cent of the cases with the use of 10 mg doses of testosterone propionate. Kurzrok and O'Connell,⁷ in a series of 21 cases to avoid the painful manifestations of lactation, obtained a 90 per cent result with

Submitted for publication January 1940

We are indebted to Dr. Ralph Shaner of the Roche-Organon Corporation, Mr. Robert Mautner of the Ciba Pharmaceutical Company and to the Schering Corporation for their generous supply of testosterone propionate

regard to symptomatology In both series no actual inhibition of lactation was noted In an effort partially to control pain and partially to effect suppression of lactation in selected cases and bearing in mind the depressing action of the male sex hormone upon the function of the anterior pituitary gland, we also have employed testosterone propionate in varying doses, both prophylactically and therapeutically, in a series of cases postpartum

Seventy-seven mothers, mostly private patients, varying in age from 19 to 45 years (average age 28 years), and consisting of 41 primiparas and 36 multiparas, were given injections of testosterone propionate from eight to 120 hours postpartum (average forty-eight hours) depending upon effect desired and degree of breast engorgement if present With this group no restrictions were placed on their fluid intake or dietary regimen Some cases were treated only when mammary engorgement became noticeable, but others whose histories indicated previous difficulties of like nature or in whom, for one reason or another, lactation was not desirable were treated prophylactically The dosage schedule employed varied from 10 to 50 mg daily, with total dosage ranging from 40 to 275 mg (Table 1) The majority of cases received 50 mg daily on two successive days, the average total dosage for the series being 87 mg Objective breast symptoms, such as engorgement, tenderness, lumpiness, and redness, were observed and recorded on a zero to 3 plus basis, representing the prominence of each symptom In the same manner subjective symptoms, such as general discomfort, fullness, soreness, heaviness, pain, and malaise, also were elicited and recorded The percentage incidence of these symptoms is displayed in the accompanying table (Table 4) Complete suppression of lactation was effected in 35 cases (50 per cent), while in 24 cases (34 per cent) only slight secretion resulted (Table 2) The remaining cases either were unaffected or leakage of milk lasted over five days A number of the latter showed slight to moderate secretion from five to ten days then ceased lactating entirely Menses returned with sur-

prising rapidity in most instances Two patients menstruated within four weeks postpartum, and practically all had their menses within two months

Analysis of symptoms shows engorgement and tenderness to be the most common objective symptoms, whereas the incidence of rubor was practically nil Heaviness was the chief subjective symptom elicited, while the percentage incidence of malaise was low Results were evaluated as poor, fair, and good, and the following brief case histories illustrate the method used and contain the criteria applied for proper classification (Table 3)

Case Reports

Case 1—Para I, aged 30, had a low forceps delivery There was a normal puerperium except for breast symptoms She complained of general discomfort, marked fullness, and soreness and heaviness of breasts which on examination were found to be slightly reddened, moderately engorged, tender, and lumpy Beginning twenty-eight hours postpartum, testosterone propionate in 25 mg doses was given intramuscularly twice daily for four days Although discomfort persisted for only twelve hours, the breasts continued to secrete for eight days This result was considered poor

Case 2—Para II, aged 25, had a low forceps delivery She complained of pain, soreness and heaviness of breasts, and general discomfort

THE INHIBITING ACTION OF TESTOSTERONE PROPIONATE IN POSTPARTUM LACTATION

ALFRED M. HELLMAN, M D , F A C S , and LEONARD F. CIMER, M D , New York City

THE male sex hormone, testosterone propionate, has been used to some extent and with varying results in the treatment of certain disorders of the mammary gland in both male and female.

Wernicke¹¹ reported the use of this hormone in 4 cases (3 with atrophied left testicle) having unilateral gynecomastia. Testosterone propionate was employed in doses of from 2½ mg twice weekly to 25 mg three times weekly according to response. Although the normal case in his series was unresponsive, of the 3 with atrophied testicle, 2 were favorably influenced. Hoffman⁶ also employed testosterone in the treatment of males with breast hypertrophy. Twenty-eight patients (ages 11 to 73) were injected with 5 to 25 mg twice a week with resultant regression in size of the mass in 14 and a degree of regression exceeding 75 per cent occurring in 9 cases. The elapsed time before complete regression occurred varied from two to five months, and the number of injections averaged twenty-eight. It was not unusual to note a regression of 50 per cent during the first four weeks of treatment. Bender² treated 12 cases of premenstrual mastopathia with testosterone propionate over a period of six months according to the following schedule: two to three days previous to the anticipated onset of breast symptoms each patient received four injections of 5 mg on alternate days, the date for initiating therapy being selected so that treatment would be discontinued two days prior to menstruation. Four cases in his series were completely and permanently relieved of their mastopathy, 6 were greatly benefited, and 2 were unresponsive. Desmarest and Capitain⁴ also administered testosterone propionate to women with premenstrual mastopathy and obtained uniformly good results. Irregular and painful menstruation concomitant with the mastopathy was relieved and cystic mammary swelling diminished. They noted that the normal menstrual cycle was not affected by therapeutic doses. Spence⁹ employed testosterone propionate in the treatment of 16 cases of masti-

tis, using doses of 25, 50, and 100 mg usually twice a week for several months. Fourteen of these cases were relieved of pain, nodules disappeared in 3 cases and in 5 cases there was a reduction in size of nodules.

Postpartum engorgement of the mammary gland is a common disorder and one frequently accompanied by considerable discomfort. In this condition, which appears from one to four days after delivery, the breasts are heavy, swollen, painful, and tender, and the overlying skin presents a reddish blue, mottled appearance. The nipples often are retracted to such a degree that the very means designed by nature to bring relief—namely, natural withdrawal of the milk secretion—becomes impossible. The usual measures for combating this disorder are elevation of the breasts, application of cold (occasionally heat) and a tightly fitting binder, restriction of fluids, low caloric diet, saline cathartics, and the administration of sedative drugs. Despite these active ministrations, the discomfort experienced during the first few days postpartum is often recalled with greater clarity than that suffered during labor itself. Although the cause of breast engorgement in these cases is largely due to venous stasis and interference with the lymphatic circulation, nevertheless a definite amount of milk secretion is present and adds measurably to the extent of the discomfort. Under stimulation of the lactogenic hormone elaborated by the cells of the anterior pituitary gland, swelling of the acinar cells of the breast takes place, the lymphatics become engorged, and the individual milk ducts become palpable. If nursing is possible or if withdrawal of the breast contents is affected by other means, the gland cells are split into globules of fat, and milk is elaborated from the neighboring lymphatics. Though the entire process is physiologic, it is frequently carried to an unpleasant extreme, especially in primiparas. Abarbanel,¹ in a series of 50 patients with severe and painful engorgement, was able to effect practically complete relief in 92 per cent of the cases with the use of 10 mg doses of testosterone propionate. Kurzrok and O'Connell,⁷ in a series of 21 cases to avoid the painful manifestations of lactation, obtained a 90 per cent result with

Submitted for publication January 1940.

We are indebted to Dr. Ralph Shaner of the Roche-Organon Corporation, Mr. Robert Mautner of the Ciba Pharmaceutical Company, and to the Schering Corporation for their generous supply of testosterone propionate.

tured spayed rats and found that the pituitary lactogen content was augmented. They feel, therefore, that the action of the male sex hormone in suppressing lactation is due neither to suppression of lactogen secretion nor to suppression of its discharge into the blood stream. Testosterone propionate may conceivably act directly through the circulatory system upon the lymphatics and veins of the mammary gland which, of course, become tremendously engorged a few days after delivery. Early menstruation in a number of cases, however, would speak for disappearance of the corpus luteum, and this in turn would seem to indicate withdrawal of the protecting influence of the lactogenic hormone, i.e., action of testosterone directly upon the anterior pituitary.

Cacciarelli³ reported the use of an ovarian extract and a preparation containing both ovarian and anterior pituitary extracts in a series of cases for the purpose of suppressing postpartum lactation. The rationale of employing a whole ovarian extract without estrogenic activity in this indication is not quite clear, though results obtained were said to be satisfactory. The use of an anterior pituitary preparation without galactotropic properties rests upon a sounder theoretical basis, since by stimulation of ovarian function the resultant elaboration of material with estrogenic activity would provide an inhibitor of anterior pituitary lactogenic action with resultant suppression of lactation. A function of the ovarian hormones is, of course, to build breast tissue, the estrogenic principle encouraging development of the duct system and the corpus luteum principle leading to alveolar and, hence, lobular growth. As long as these hormones are circulating in sufficient concentration in the blood, however, the process of lactation itself is held in abeyance. The action of the male sex hormone is similar in character.

Summary

1 The male sex hormone, testosterone propionate, was employed to suppress postpartum lactation in a selected but representative group of 77 mothers.

2 Breast symptoms, both subjective and objective (if slight complaints are ignored), were prevented in a large percentage of patients where the administration of testosterone was begun early and was employed as a prophylactic measure. A high percentage of patients already lactating responded promptly to the application of testosterone.

3 Forty-eight hours postpartum was found to be the average optimum time for initiating therapy in this indication, though an occasional case would seem to demand earlier medication for effective suppression of secretion and prevention of untoward symptoms.

4 An average dose of 87 mg per patient was found to have optimum milk inhibiting activity, though dosage schedules were naturally varied to meet individual requirements.

5 No undesirable aftereffects of testosterone medication were noted in any of our cases.

PREVALENCE OF TRICHINOSIS

The surprising estimate that one out of every six Americans is infected with the trichinosis parasite is made by the United States Public Health Service, according to a release sent out by Senator Thomas C. Desmond, chairman of the New York State Trichinosis Commission, first of its kind in the country. He says:

Our commission will investigate all phases of trichinosis, including five suggested preventives: (1) skin tests on hogs to determine whether or not they are infected, (2) compulsory cooking of garbage before it is fed to hogs, (3) microscopic inspection of all pork products, (4) required

refrigeration of hogs immediately after slaughter, and (5) state meat inspection similar to the federal service.

"One of the first activities of the State Trichinosis Commission will be to examine hundreds of hot dogs, hamburgers, pork sausages, and other pork products made and sold in New York State. This examination will help determine whether processing of intrastate pork to eliminate the trichinosis parasite should be required and whether the mixing of pork in hamburgers, often mentioned by medical authorities as a cause of trichinosis, should be stopped."

Her breasts were moderately tender, slightly engorged, and lumpy. Beginning thirty-three hours postpartum, testosterone propionate, 50 mg, was given on the first day followed by 25-mg doses on each of the next two days. Although no leakage of milk occurred, the severity of subjective and objective symptoms led to the classification of the result in this case as only fair.

Case 3—Para I, aged 23, had a spontaneous delivery with total absence of subjective and objective symptoms. Beginning thirty-seven hours postpartum, testosterone propionate was administered according to the following schedule: 50 mg during the first twenty-four hours and 25 mg daily for the next two days. All symptoms remained in abeyance and no lactation occurred. Results in this case were classified as good.

Case 4—Para II, aged 31, had a spontaneous delivery. There was a normal puerperium with exception of breast symptoms. Although the patient complained of no general discomfort, the breasts were seen to be definitely engorged and were tender to pressure. Beginning sixty-five hours postpartum, testosterone propionate in 25-mg daily doses was administered for three days. No other measures were employed. The fact that all symptoms subsided, that the breasts began to soften in twenty-four hours, and that very slight lactation persisted for only three days led to the classification of results obtained in this case as good.

Case 5—Para I, aged 32, had a high forceps delivery. There was an entirely normal puerperium. Beginning thirty-six hours postpartum, testosterone propionate in 50 mg doses was administered daily for two days. There were absolutely no breast symptoms, either objective or subjective, and no leakage of milk. Result was classified as good.

Case 6—Para II, aged 34, had a spontaneous delivery. There was a normal puerperium except for breast symptoms. Six and one-half days postpartum, during which time patient had attempted unsuccessfully to nurse infant, breasts became painfully engorged, tender, and moderately heavy and lumpy. One injection of testosterone propionate, 25 mg, brought about complete relief within twelve hours. The results obtained in this case, therefore, were classified as good.

Case 7—Para XIII, aged 45, had a breech delivery. There was a normal puerperium. Despite the fact that the patient had successfully nursed 10 babies, the administration, beginning forty hours postpartum, of testosterone propionate in 50-mg doses on two successive days forestalled, in large measure, the development of usual breast symptoms, and secretion of milk was entirely prevented. The results were classified as good.

Case 8—Para I, aged 26, had a spontaneous delivery. There was a normal puerperium except for breast symptoms which developed on

the third postpartum day. A total of 125 mg of testosterone propionate was administered without apparent effect. The results were classified as poor.

Case 9—Para I, aged 29, had a midforceps delivery. The puerperium was complicated by development of endometritis. Administration of testosterone propionate (75 mg) beginning seventy-two hours postpartum was followed by only slight breast engorgement which persisted for about eight hours. There was no milk secretion. The results were classified as fair.

Case 10—Para II, aged 32, had a cesarian section. There was a normal puerperium except for breast symptoms as described. Treatment was started forty-eight hours postpartum. Breasts were soft and unengorged until the end of fifth day when they filled. They softened immediately with further therapy, but upon cessation they again became engorged, again softened with more testosterone, and remained soft thereafter. A total of 275 mg was given. The results were considered fair but very interesting because of the response to therapy.

Many cases responded dramatically to treatment with testosterone propionate during the puerperium, symptoms both subjective and objective being held entirely in abeyance and the secretion of milk being effectively arrested. One case gave a perfect response to only four daily injections of 10 mg each, secretion being controlled and normal menses beginning six weeks postpartum. On the other hand, 1 case, a Para II, aged 32, required the administration of 275 mg in divided daily doses to control her breast symptoms which finally subsided on the eighth day.

Discussion

In many instances it is highly desirable to suppress postpartum lactation. Patients with persistent soreness or deformation of the nipples and with histories of breast disorders during previous pregnancies, patients whose infants expired sometime previous to or actually during labor, and patients who for various social or economic reasons refuse to nurse their offspring, all these welcome the application of effective milk inhibiting measures.

Inhibition of lactation and prevention of breast engorgement during the puerperium were effected in an important percentage of our cases by the use of the male sex hormone, testosterone propionate. The mechanism of action may be one of depression of function of the anterior pituitary, thereby reducing the amount of circulating lactogenic hormone. On the other hand, Reece and Mixner³ employed testosterone propionate in 200 gamma daily doses for fifteen days on sexually ma-

FIGS 1 and 2 CASE 3

In the survey, consultation, and diagnostic service rendered by the Bureau of Tuberculosis of the Department of Health, we have occasion to see and interpret the chest x-rays of many thousands of people. These people range in age from infancy to old age and represent a reasonably accurate cross section of the poor and middle-class population of New York City.

In these x-ray plates we have been impressed by the not infrequent finding of radiologic densities, undoubtedly abnormal, without the patient showing any constitutional disturbances. These findings appear, progress, and resolve in a period of weeks or months. From the x-ray point of view they resemble most closely those cases described by Smiley⁷ and Bowen.⁸

From the clinical point of view they correspond most closely to those suggested by Majors⁴, Bowen⁸, and to a lesser extent Allen.⁵

We hasten to add that these cases are by no means completely studied. It is beyond the scope of the Chest Service to do blood counts, cultures, sputum typing, etc., or even follow these cases for an indefinite period of time. Nevertheless, insofar as we have been able to observe—the radiologic appearance and disappearance of the lesion, the course of the disease, the physical signs, complete resolution in a comparatively short time, etc.—we feel that these cases belong somewhere in the family of the pneumonias, despite the fact that they were afebrile and asymptomatic and that resolution occurred without therapy.

The cases that follow were studied at the various consultation and diagnostic clinics of the Board of Health of the City of New York.

Case Reports

Case 1—M. T., white man, aged 22, reported to the Central Chest Clinic on May 12, 1939,

because a survey x-ray taken on April 3, 1939, revealed an infiltration in the fourth and fifth left interspaces near the periphery. This area was soft and mottled. He stated that he felt fine. He admitted that he had a slight cold in April when his first x-ray was taken but denied being ill with it. He vigorously denied any illness within the past few months. His past history revealed a pleuropneumonia of the lower lobe of the right lung four years ago. He also admitted being susceptible to occasional "grippe." He had lost no weight, had no chronic cough, never had hemoptysis, etc. His family history was essentially negative.

Physical examination revealed a well-nourished man. His temperature was 98 degrees, pulse, 78 per minute, and respirations, 20 per minute. His weight was 156 pounds and height was 5 feet 10 inches. There was no dyspnea or cyanosis. Chest examination revealed some impairment of resonance over the lower lobe of the left lung with few transient subcrepitant rales. The Mantoux test (0.10 mg.) with old tuberculin was negative, and 1.0 mg. two days later was only slightly positive. Repeated sputums for tubercle bacilli were negative. Sputum typing revealed pneumococci above type XXXII. An x-ray at this time, May 12, 1939, showed complete clearing of the area described above.

Case 2—D. L., white girl, aged 18, was called to the Central Chest Clinic because a routine survey chest x-ray on March 30, 1939, revealed patchy infiltration of upper lobes of both lungs, most marked in the right lung.

She appeared at the clinic on May 11, 1939, and stated she felt fine, had no cough, no fever, no sweats, and no loss in weight. She admitted having had a cold in March, 1939. Her past history and family history were negative.

Examination revealed a well-nourished girl, not apparently ill. Her weight was 116 pounds and height was 5 feet 3 inches. Her temperature was 99.4, pulse, 100, and respirations, 20. There were no abnormal physical signs. An x-ray taken at this time revealed clearing of the affected areas. Sputums were negative for the tubercle bacillus, and no organisms were re-

ATYPICAL PNEUMONIAS

HARRY FREDD, M D , Brooklyn

VOLUMES have been written on the pneumonias. Tremendous advances have been made in the study and conquest of these diseases. And yet the clinical picture given us by Hippocrates¹ of "acute fever, cough, pain, sputum and tendency to get well in a week" remains essentially our clinical picture today.

Today, the emphasis in pneumonia is on etiology rather than the clinical picture, for our serotherapy, and to a lesser extent chemotherapy, depends upon the causative agent.

Nevertheless, if we are to get a true concept of the incidence of pneumonia, some emphasis must be placed upon the recognition of all atypical types.

It is true that many atypical pneumonias have been described. The common ones are well known, and yet we have been impressed by an atypical type of pneumonia that has not been clearly defined. This type is afebrile, is asymptomatic, and depends upon x-ray study of the chest for its discovery.

A review of the literature yields little reference to this type of atypical pneumonia.

As far back as 1910 Tuller² called attention to an afebrile type of pneumonia occurring in certain individuals. However, his cases did not quite correspond to ours. His findings occurred only in debilitated individuals, and persons suffering from alcoholism, nephritis, etc. Furthermore, he felt, that the normal temperature of his patients was below 98.6 degrees. Therefore, a temperature of 100 degrees might correspond to a temperature of 102 degrees in so-called normal individuals. In all his cases some severe systemic intoxication antedated the onset of the pneumonia.

Similarly, Farroni³ recorded an afebrile pneumonia in 1910, but the picture he described was one of typical pneumonia without fever and was in no way similar to the cases we will describe.

In 1927 Majors⁴ called attention to atypical pneumonias without temperature disturbance, without chill, and with little or no pain. However, his discussion of atypical pneumonia concerned itself mainly with the gastrointestinal, meningitic, and abdominal symptoms in pneumonic children rather than the

classic textbook symptoms of pneumonia. Nevertheless, his conclusion was that "numerous cases of atypical pneumonia come under our care, terminating either in death or recovery, without our being able to detect the existence of the disease." We are in complete agreement with this statement, although none of our patients have died.

Probably the cases we are about to describe fit in best with those so carefully discussed by Allen⁵ in 1936. He grouped these cases under the name "acute pneumonitis." These he defined as "respiratory infections, benign in course, with few physical signs, and x-ray evidence of localized pulmonary involvement."

In his excellent paper Allen described a group of 68 cases. However his patients were febrile, had all the classic symptoms of influenza, apparently required hospitalization, and some developed complications. But the diagnosis of pneumonia in his cases, could be made only by x-ray—a finding identical with ours.

Similarly, Bowen⁶ stated that 5 to 25 per cent of influenza cases developed "pneumonitis." He felt that systematic x-ray of even mild influenza cases (headache, backache, malaise, temperature above 100 degrees, injected pharynx, etc.) would show a "pneumonitis." In his opinion this occurred in a high percentage of cases, and resolution was complete within two weeks. However, his records revealed many severe cases that ultimately had typical pneumonic symptoms and signs, and death occurred in some of these. Our cases resemble his closely, at least from the roentgenologic point of view. However, our patients had no definite influenza so far as we could determine, they took much longer to resolve, and none died.

While this paper was being prepared, we were happy to find an article by Smiley and his associates⁷ on "acute interstitial pneumonitis." However, his cases were febrile, more communicable, and more toxic. Here, too, the x-ray pictures described by him were very similar to our own. Without a doubt our cases probably represent a mild grade of the condition he described.

Similarly, Reimann⁸ described cases that resembled ours from the x-ray point of view. But his atypical pneumonias were more toxic, dyspneic, and febrile.

From the Central Chest Clinic, Bureau of Tuberculosis, Department of Health New York City

sultation Service for diagnosis on April 12, 1939. Examination revealed an undernourished man, not acutely ill. His temperature was 98 degrees, pulse, 82, respirations, 24, weight, 118 pounds, and height, 5 feet 5 inches. An x-ray plate revealed patchy infiltration in the left third and fourth interspaces, with parenchymal mottling from the hilum to the periphery. Sputums were negative for tubercle bacilli. Resolution was complete on May 11, 1939.

Case 11—R. R., white boy, aged 6, came into the Diagnostic Clinic on April 20, 1939, complaining of cough and moderate expectoration of one week's duration. His temperature was 98 degrees, pulse, 94, and respirations, 24. Dullness and rales were present over the lower right lung field. An x-ray revealed confluent densities along the right border of the heart in the medial portion of the lower lobe of the right lung. On May 20, 1939, roentgenologic study showed this area to have completely resolved.

Case 12—M. G., white man, aged 37, complaining of cough and copious expectoration of three weeks' duration came to the Diagnostic Clinic on November 16, 1938. His temperature was 98 degrees, pulse, 100, respirations, 22, and weight 143 pounds. Dullness, crepitant rales, and bronchovesicular breathing were present over the lower right lung field. An x-ray (Fig 3) at this time revealed bronchopneumonic infiltration of the lower lobe of the right lung. On December 7, 1938, all signs had cleared. An x-ray confirmed this clearing.

Case 13—V. R., white boy, aged 9 was examined as a contact in 1936, 1937, and 1938. The Mantoux test was negative. Sputums and x-ray were negative on February 21, 1939, and the patient was discharged. On January 10, 1938, he had developed an area of infiltration, patchy in distribution, in the left fourth and fifth interspaces. He had had a cough, but was not ill and had had no fever. This area cleared completely in two months and his Mantoux test and sputums remained negative.

Case 14—M. G., Negro, aged 36, came into the Diagnostic Clinic on November 16, 1938, complaining of cough and expectoration. His temperature was 99 degrees, pulse, 96, and respirations, 24. Examination revealed dullness, bronchovesicular breathing, and numerous rales over the upper left lung field (Fig 3). Sputums were negative for tubercle bacilli. An x-ray revealed an area of density from the third to the fourth left anterior ribs extending from the periphery to the hilum. The diagnosis at this time was lobar pneumonia. An x-ray on January 10, 1939, showed this area to be entirely cleared.

Case 15—B. L., white girl, aged 20, came into the clinic for diagnosis on March 30, 1939. Her chief complaints were cough and pain in the left chest of two months' duration. Her temperature was 99 degrees, pulse, 100, respirations, 22, weight, 150 pounds, and height, 5 feet 5 inches. Repeated sputum examinations were negative

FIG 3 CASE 14.

for tubercle bacilli. No typing was done. Physical examination revealed a well-nourished girl, not acutely ill. There was some impairment of the resonance over the upper lobe of left lung, anteriorly, with a few subcrepitant rales (Figs 4 and 5). An x-ray showed infiltration in the left first and second interspaces. This patient returned on May 8, 1939. An x-ray and examination at this time showed complete clearing.

Case 16—C. D., white girl, aged 7, came into the Diagnostic Clinic on February 27, 1939, complaining of cough with yellowish expectoration of three weeks' duration. Her temperature was 98.8 degrees, pulse, 84, and respirations, 20. Examination revealed an undernourished girl, not acutely ill. Dullness was present over the right side of the chest, posteriorly. Numerous moist rales were present here. These rales were also audible over the lower lobe of the left lung, posteriorly. An x-ray at this time revealed patchy infiltration over lower lobes of both lungs. Her sputums were negative for tubercle bacilli. No typing was done. She returned on April 21, 1939, and had gained 7 pounds. Examination, as well as x-ray at this time, revealed complete clearing.

Case 17—M. W., white girl, aged 20, was called to the clinic because a survey x-ray on May 10, 1939, revealed a uniform dense area over the left sixth and seventh interspaces, anteriorly, near the periphery of the lung. Sputums were negative for tubercle bacilli. When she reported on June 8, 1939, typing of sputums revealed no organism. She denied all recent or present illness. Physical examination revealed, at this time, bronchovesicular breathing, dullness over the lower left lung field, but no rales. She stated that she had had a cold with moderate expectoration on May 10, 1939 (when the survey x-ray was taken). An x-ray on June 8, 1939, was entirely negative.

Case 18—I. P., white boy, aged 19, had a survey x-ray taken on May 12, 1939, which revealed

vealed when her sputums were sent for study and typing

Case 3—S S, white boy, aged 16, was called into the Central Chest Clinic because a routine chest x-ray on February 7, 1939, revealed a questionable increase in the transverse diameter of the heart

He came in on March 9, 1939, and stated that he had had a cold for the past week, with moderate expectoration and some pain in the right lower part of the chest. He had had no fever, was not short of breath, and did not feel bad in any way. His past and family history were negative.

Physical examination revealed a well-nourished boy, weight 157 and height 5 feet 10 inches. His temperature was 98 degrees, pulse, 78, and respirations, 18. Examination of the chest revealed dullness over the upper lobe of the right lung with few rales. An x-ray at this time (Figs 1 and 2) revealed a fan-shaped area of infiltration with apex toward the hilum. His sputums were negative for tubercle bacilli.

He was recalled on March 27, 1939, and the affected area had completely resolved. No further sputum study could be made as the patient would not cooperate.

Case 4.—D U, white man, aged 44, reported on April 20, 1939, for a check-up because of a healed tuberculous lesion at the right apex. He stated that he had been coughing for the past few weeks, with moderate expectoration. He admitted that he had had a few blood specks in his sputum during the past month. His past history dated from 1918 when he was "gassed" in the World War and subsequently learned that he had a few scars at the right apex and in the right lung.

Physical examination revealed him to be moderately well-nourished and apparently not ill. There were dullness, diminished breath sounds, and numerous rales in the lower lobe of the right lung. His temperature was 98 degrees, pulse, 100, and respirations, 20. Repeated concentrated sputums were negative for tubercle bacilli. An x-ray at this time revealed mottled infiltration in the right second, third, and fourth interspaces. There was a small nodular infiltration of the right apex.

On May 8, 1939, he had gained 3 pounds, still had his cough, and felt weak. An x-ray showed a complete clearing of the affected area.

Case 5—I S, white man, aged 58, was called into the Central Chest Clinic because a routine survey x-ray on April 17, 1939, revealed a fan-shaped area of infiltration in the right second and third interspaces with the apex toward the hilum. The patient complained of some cough with moderate expectoration, which he attributed to the "grippe." His past and family history were negative. Examination and x-ray on May 31, 1939, revealed a clearing of the affected area.

Sputums were negative for tubercle bacilli and revealed pneumococci above type XXXII.

Case 6—E E, Negress, aged 12, came into the Diagnostic Service on January 7, 1939, complaining of cough of four days' duration, moderate expectoration, and a cold for two weeks. Her temperature was 98 degrees, pulse, 102, respirations, 24, and weight, 83 pounds. Physical examination revealed a moderately well-nourished girl, not acutely ill. There were dullness and numerous crepitant rales over the lower lobe of the left lung. Sputums were negative for tubercle bacilli. An x-ray at this time revealed an irregular area of patchy infiltration in the lower lobe of the left lung. The patient returned on February 23, 1939, and had gained 9 pounds in weight, the lung signs had disappeared, and the area in question had cleared on x-ray study.

Case 7—M K, Negress, aged 33, came into the Diagnostic Clinic on June 29, 1938, complaining of cough and moderate expectoration. Repeated sputums were negative for tubercle bacilli. Her temperature was 99 degrees, pulse, 100, and respirations, 22. An x-ray at this time revealed a small area of patchy consolidation in the median one-third of the lower lobe of the right lung. There was dullness over this area and a few rales. Two weeks later she returned, and the area shown on x-ray was apparently clearing. Resolution was complete on August 12, 1938.

Case 8—K J, Negress, aged 31, complaining of cough of two weeks' duration with moderate expectoration, which she attributed to a post-nasal drip. Physical examination revealed her to be well-nourished and not acutely ill. Her temperature was 98 degrees, pulse, 80, respirations, 20, and weight 149 pounds. Dullness and numerous rales were present over the lower left lung field, posteriorly.

On February 23, 1939, the infiltration appeared more extensive in the lower lobe of the left lung, but three weeks later an x-ray showed this area to be entirely cleared. All sputums were negative for tubercle bacilli.

Case 9—B D, white man, aged 29, complained of a cough of one week's duration which was short, hacking, and irritating but not productive. His temperature was 99 degrees, pulse, 80, and respirations, 18. Scattered rales were present over the lower lobe of the left lung. At this time, April 20, 1939, an x-ray revealed a patchy infiltration in the chest over the lower lobe of the left lung, anteriorly. The blood count showed 19,000 white cells of which 85 per cent were polymorphonuclear leukocytes. Sputums were negative for tubercle bacilli. Streptococcus hemolyticus was found in the sputums. On April 27, 1939, this area had entirely resolved. This patient had been put to bed, although he was afebrile, and had had sulfa-pyridine therapy for three days.

Case 10—A D, Negro, aged 25, had complained of a cold of two weeks' duration, with questionable fever. He came to the Con-

or a rounded area of moderate density, beginning at the hilum, extending to the periphery, and usually appearing in the basal portion of a lobe

We feel that these represent a true infiltration of the lung rather than an allergic response as Davidson⁹ feels

Conclusion

1 A series of 23,463 chest x-rays were studied, and 64 cases of asymptomatic "pneumonia" were discovered

2 These cases were represented by radiologic densities with no constitutional disturbances and obscure physical signs of pneumonic involvement

3 These findings appear, progress, and resolve completely without any therapy within two months

4 Differentiation from atelectasis, epituberculosis, exudative tuberculosis, and infarcts is difficult, but none of these diagnoses could explain these cases satisfactorily

5 The importance of chest x-ray in general infections (Davidson⁹) and most par-

ticularly in so-called infections of the upper part of the respiratory tract cannot be over-emphasized We are convinced that many cases of lung involvement, now unrecognized, would in this way be discovered

. . .

I wish to thank Dr H R Edwards, Director of the Bureau of Tuberculosis of the Department of Health, City of New York, for his constructive criticism

THE MEDICAL SIMILE

From a critique by S J Perelman in P M

The sensations one undergoes while reading a movie magazine are like nothing else on earth. They are somewhat akin to inhaling dental gas or being cupped by an inept barber, and yet they suggest eating a banana under the water.

The stifling pressure, the intolerable suspicion

that the brain has burst, and the creeping paralysis of the motor nerves are as marked as though you were suffering an attack of the "bends." For all I know somebody may have invented a decompression chamber to accustom the mind by degrees to movie magazines. There's room for one — J.A.M.A.

Prize Essays

THE Lucien Howe Prize will be open for competition at the next Annual Meeting of the Medical Society of the State of New York, April 28, 1941, in Buffalo. This prize of \$100 will be presented for the best original contribution on some branch of surgery, preferably ophthalmology. The author need not be a member of the Medical Society of the State of New York. The following conditions must be observed:

Essays shall be typewritten or printed and the only means of identification of the author shall be a motto or other device. The essay shall be accompanied by a sealed envelope having on the outside the same motto or device and containing the name and address of the writer.

If the Committee considers that no essay or contribution is worthy of the prize, it will not be awarded.

Any essay that may win the prize automatically becomes the property of the Medical Society of the State of New York "to be published as it may direct."

All essays must be presented no later than February 1, 1941, and sent to the Chairman of the Committee on Prize Essays of the Medical Society of the State of New York, 292 Madison Avenue, New York.

CHAS GORDON HEYD, M D, *Chairman, Committee on Prize Essays*

FIGS 4 and 5 CASE 15

bronchopneumonic infiltration in the right lung in the region of the fifth and sixth anterior interspaces

He reported to us on June 13, 1939. There was no history of any pneumonia, no infection of the upper part of the respiratory tract, and no sinus infection. There was no cough and no expectoration. No fever and no loss in weight could be elicited. Examination at this time revealed a well-nourished boy, not apparently ill. There were no abnormal chest findings. An x-ray at this time revealed clearing of the affected area. Sputums were negative for tuberculosis.

Case 19—H. M., Negress, aged 20, was called into the Central Clinic because a survey x-ray plate in May, 1939, revealed definite infiltration in the left second and third anterior interspaces near the periphery of the lung. Her history revealed no evidence of infection of the upper part of the respiratory tract and no sign of sinus infection. There was no history of pneumonia or tuberculosis. She had lost no weight and felt fine. There were no sweats, no fever, no pain, and no amenorrhea. Examination on June 11, 1939, revealed her to be undernourished but not apparently ill. There were no abnormal physical signs, and an x-ray revealed complete clearing. All sputums were negative for tubercle bacilli.

Discussion

In order to find the prevalence of this type of "pneumonia," we analyzed a group of 23,465 chest x-rays and reports,* taken in Lower Harlem Health Center between 1936 and 1938. This group was obtained from a larger series of 65,459 cases that had been x-rayed and studied to determine the prevalence of pulmonary tuberculosis.

* Statistics taken from records compiled by WPA funds for the Chest Service of the Department of Health of the City of New York.

We found 64 cases of radiologic opacities in this group. They had no constitutional disturbances, no symptoms, and were completely resolved within two months. Fully one-third of these fell in the adult negro group. These cases, we feel, are atypical pneumonias. While this incidence is not great (0.272 per cent), it must be remembered that these cases were discovered accidentally, among so-called "well" people. It is probable that if serial x-rays were taken, especially during seasons when respiratory diseases are common, many more cases might be found.

The differential diagnosis of roentgenologic opacities as described above is quite difficult. Atelectasis, epituberculosis, exudative tuberculosis, infarcts, etc., cannot always be ruled out. Nevertheless, in studying the cases compiled, we feel that none of these diagnoses could satisfactorily explain these cases.

Furthermore, we feel that these cases do not belong under the atypical pneumonias described in textbooks: the abortive type with the acute fever, herpes, cough, and rapid resolution; the asthenic type in old people with little fever and marked constitutional disturbances; the hypostatic type or terminal pneumonia; or even the allergic type with its history of allergy, eosinophilia, and epinephrine response.

It is our opinion that there is a mild type of pneumonia of inconstant etiology occurring in individuals who have mild infections of the upper part of the respiratory tract presenting no constitutional disturbances and that it is discovered only by x-rays of the chest.

This x-ray evidence will present at least a hazy opacity in the lung. At times this may take on the appearance of a mottled fan

strains were identified (116.9 per cent)—199 by direct examination and 178 by mouse inoculation. Seventeen strains were unclassified.

The interval between collection and examination of a specimen was of no importance in the success of determining pneumococci when the time was less than two days. When three or more days had elapsed, however, pneumococci were found in fewer specimens, and fewer types were identified. A comparison of the findings by direct examination and by animal inoculation with reference to the age of the specimen is given in Table 1. The data indicate that with older specimens one may expect to find pneumococci

more readily by the direct Neufeld test than by mouse inoculation. Of 181 strains in specimens two days old, 98 were typed on direct examination and 83 by mouse inoculation, of 26 strains found in specimens three or more days old, 16 were typed on direct examination and only 10 by mouse inoculation.

Incidence by Serologic Type—The incidence, in order of frequency, by serologic type of the 377 strains identified was as follows: types III, XIX, XV, VI, VIII, XI, XX, XXIX, XIII, XVIII, X, XVI, XVII, XXII, IV, XXI, XXIII, XXIV, IX, I, VII, XXVIII, XIV, XXVII, XXXI, II, V, XII, XXV, and XXXII. Seventeen additional strains were unclassified.

THE INCIDENCE OF TYPES OF PNEUMOCOCCI IN SPUTUM FROM PATIENTS WITH RESPIRATORY INFECTIONS OTHER THAN PNEUMONIA

ILIE ARDELEAN, M D, Cluj, Rumania

DATA in regard to the types of pneumococci that are harbored by various groups of individuals are of importance as a basis for evaluating the significance of laboratory findings in the study of specimens from patients with pneumonia. With this in mind, a survey was undertaken of specimens of sputum submitted to be examined for tubercle bacilli from individuals with respiratory infections other than pneumonia. The purpose of the investigation was to add to the data compiled by other workers¹⁻⁷ who have attempted to evaluate the etiologic significance of the so-called higher types of pneumococci encountered in the sputum of patients with lobar or bronchopneumonia. Another purpose was to determine whether these higher types of pneumococci have any epidemiologic significance in the pathogenesis of the disease.

Procedure

During a six-month period (October, 1937, to March, 1938) from four to six specimens were chosen at random from among those received daily in the diagnostic laboratories from various parts of New York State for routine examination for tubercle bacilli. Those in transit for more than two or three days were not considered. Care was taken to include but one specimen from a patient, only first specimens being selected.

From the accompanying history forms, data regarding the clinical condition of the patient were recorded. In nearly all cases, respiratory, subacute, or chronic symptoms and positive physical findings were noted. The physicians' diagnoses were suspected tuberculosis, definite tuberculosis, or "probably not tuberculosis."

The technic was similar to that employed for typing pneumococci in sputum from patients with pneumonia. Each specimen was tested by the Neufeld method with the

thirty types of serum (Cooper⁸) *. Specimens that failed to show pneumococci by this means and the majority of those in which types were determined were injected intraperitoneally into mice. One milliliter of sputum diluted 1:2 with saline solution was used. All animals that had not died spontaneously within forty-eight hours were chloroformed at this period, and the peritoneal washings were examined by the Neufeld procedure. Cultures on blood-agar plates were prepared from the peritoneal exudate and from the heart's blood of all the mice. Single colonies were fished when the colonial characteristics indicated the presence of more than one type of pneumococcus, the fishings were placed in dextrose-serum broth and tested by the Neufeld reaction after eight hours' incubation. When a reaction was obtained with more than one type of serum, single colonies were isolated in pure culture to determine whether more than one type of pneumococcus was present in the same specimen or whether one strain reacted with two or more types of serum. If no type was identified with the thirty standard types of serum, bile-solubility and muhn-fermentation tests were made before any microorganism was considered an unclassified strain of pneumococcus. No attempt was made to isolate and type pneumococci by culturing the sputum on blood-agar plates or in Avery's broth.

Results Obtained in a Study of 500 Specimens

The results obtained in a study of 500 specimens have been analyzed according to findings obtained by the Neufeld method for pneumococcus-type differentiation, the incidence of types and their distribution with relation to epidemiologic data—for example, season, patient's age, and sex, frequency of types in sputum containing tubercle bacilli, multiple types in the same specimen, cross reactions, and unclassified strains.

Findings Obtained by the Neufeld Method—Pneumococci were found in 337 specimens (67.4 per cent). From these specimens 394

Seventeen additional strains were unclassified.

TABLE 3—DISTRIBUTION ACCORDING TO SEX OF PATIENT, OF 394 STRAINS OF PNEUMOCOCCI FROM 500 SPECIMENS

Specimens Examined	Pneumococci Found		Strains Identified	
	Number	Per-centage	Number	Per-centage
298 Men	221	74.2	268	121.2
202 Women	116	57.4	126	108.6
Total	337	67.4	394	116.9

Seasonal Variation in Prevalence of Pneumococci—During the six-month period, the number of specimens in which pneumococci were found varied from month to month. There was a marked increase from a minimum incidence in October (54.5 per cent) to a maximum in March (77.4 per cent). The greatest percentage of strains was found in February, when, in 48 specimens containing pneumococci, 64 strains were identified. The distribution of the types most prevalent in this series was relatively uniform in the various months. The types less frequently identified—I, II, V, VII, XIV, XXIII, XXV, and XXXII—were found in December, January, February, and March (Table 2).

Distribution of Pneumococci According to Sex of Patients—The prevalence of pneumococci in specimens from men was higher than in those from women. Not only did the percentage of specimens containing pneumococci differ (74.2 per cent men, 57.4 per cent women) but also the number of strains typed (121.2 per cent against 108.6 per cent) (Table 3).

Distribution of Types According to Age of Patients—Since the majority of the patients were adults and relatively few were under 10 to 19 years of age, the distribution of types according to age groups is less significant. Perhaps the fact that types I, II, VII, and XIV occurred only in persons under 49 years

old should be mentioned, because the other types prevailed with more or less fluctuation through all age groups.

Distribution of Types in Specimens Containing Tubercle Bacilli—Tubercle bacilli were found in 66 (13.2 per cent) of 500 specimens examined by the Ziehl-Neelsen stain. In 34 of these specimens, 42 strains of pneumococci were identified, the incidence of types was in general the same as in the entire series.

Multiple Pneumococcus Types—More than one type occurred in 50 or 14.8 per cent of the specimens in which pneumococci were found, in 44 specimens, two different types were identified, in 5, three, and in 1, four. The 107 strains are listed in Table 4 according to their distribution in the specimens.

Cross Reactions—Forty strains (10.2 per cent) were found to give a reaction either by a *Quellungsreaktion* or agglutination with two types of serum. The number of such strains and types, as well as the reaction obtained, is illustrated in Table 5. The importance of this problem is more than theoretic.

Unclassified Strains—Of 394 strains of pneumococci identified, 17 did not react with the standard types of serum, although 12 of them were found to agglutinate in serums produced from 3 unclassified strains isolated previously—7 with one, 3 with a second, and 2 with a third. In addition to the 12 strains identified with the serums mentioned, 5 strains remain unclassified, which in the total strains represent a percentage of 1.3.

Discussion

Although the incidence of various types of pneumococci in lobar pneumonia varies from year to year,^{3,6} nevertheless, each type may hold a fairly uniform position in order of

TABLE 4—FREQUENCY AND DISTRIBUTION OF 107 TYPES OF PNEUMOCOCCI IN 50 SPECIMENS WITH MULTIPLE TYPES

frequency Thus, from the consistent results of Finland³ and Bullock and Wilcox,⁴ Lord and Heffron⁵ reached the conclusion that types I, III, II, V, VIII, VII, IV, XIV, IX, and XVIII were, in the order named, the most common types encountered as incitants of lobar pneumonia in adults. Of these, types III, VIII, XVIII, IV, and IX prevail also in a significant percentage in the nasopharynx of carriers^{6,10} and of individuals with respiratory infections other than pneumonia.^{2,6} Consequently, little epidemiologic importance can be attributed to the last types mentioned. The results obtained in the present survey are in agreement with the classification of pneumococci in specimens from normal persons, since in the frequency range of the thirty types, type I is twentieth, type III, first, type II, twenty-sixth, type V, twenty-seventh, type VIII, fifth, type VII, twenty-first, type IV, fifteenth, type XIV, twenty-third, type IX, nineteenth, and type XVIII, tenth. Furthermore, types I, II, V, VII, and XIV were found in those months in which the incidence of lobar pneumonia is highest.

Difference in the prevalence of pneumococci in the throats of healthy people according to sex is mentioned Gundel and Okura¹¹ found much more frequent occurrence of these bacteria in boys than in girls. In groups of men, Powell, Atwater, and Felton¹² encountered pneumococci in 66 and 67 per cent of the individuals studied and 53 per cent in groups of women. Too much importance cannot be placed on this difference, however, as an explanation of the much higher incidence of pneumonia in men than in women.¹³

The difficulty that arises when more than one type is recovered from the sputum of individuals with lobar pneumonia is evident. Andrews⁴ found more than one type in the throats of half of the children with lobar pneumonia—an incidence far higher than Finland reported for adults.¹⁴

Problems presented by cross reactions due to the serum used for typing in the Neufeld or agglutination tests can be eliminated to a certain extent by determining the *Quellungreaktion* and agglutination titer of serum against the homologous type—that is, by testing the serum adequately for such reactions before it is used in diagnostic examinations. When the cross reaction results from an antigenic relationship of some of the types—for example, types III and VIII, II and V—the demonstration of such a relationship might aid in estimating the etiologic significance

of the types and be of value in the study of the antigenic properties of the pneumococcus.

Summary

A survey was undertaken during a six-month period (October, 1937, to March, 1938) of the prevalence and distribution of the types of pneumococci in sputum submitted to be examined for tubercle bacilli, the Neufeld method was used for the type differentiation.

In 337 (67.4 per cent) of 500 specimens studied, 394 (116.9 per cent) strains of pneumococci were identified—199 on direct examination and 178 by mouse inoculation.

The time interval between collection and examination of the specimens was of no importance in the success of determining pneumococci when the time was one or two days, when three or more days elapsed, fewer were typed.

The incidence of types in order of frequency was III, XIX, XV, VI, VIII, XI, XX, XXIX, XIII, XVIII, X, XVI, XVII, XXII, IV, XXI, XXIII, XXIV, IX, I, VII, XXVIII, XIV, XXVII, XXXI, II, V, XII, XXV, and XXXII.

Seventeen strains did not react with the

standard types of serum Twelve of them were found to agglutinate in serums from 3 unclassified strains isolated previously

The seasonal incidence of pneumococci varied markedly from a minimum in October to a maximum in February and March Types I, II, V, VII, XIV, XXIII, XXV, and XXXII were found in the months of December, January, February, and March

The prevalence of pneumococci was higher in men than in women

The distribution of various types according to age groups was more or less uniform, with the possible exception of types I, II, VII, and XIV, which were found only in patients under 49 years of age

In specimens containing tubercle bacilli the incidence of types was relatively the same as in the entire series

Multiple pneumococcus types occurred in 14.8 per cent of the specimens in which pneumococci were found

Some of the strains (10.2 per cent) reacted with varying intensity with two types of serum

INTELLECTUAL GLANDS OF ANTIQUITY

Behold the mighty dinosaur,
Famous in prehistoric lore,
Not only for his weight and strength
But for his intellectual length
Each will observe by these remains
The creature had two sets of brains,
One in his head, the usual place,
The other at his spinal base.
Thus he could reason a priori,
As well as posteriori,
No problem bothered him a bit,
He made both head and tail of it.
So wise he was, so wise and solemn,
Each thought filled just a spinal column,
If one brain found the pressure strong,
It passed a few ideas along
If something slipped his forward mind,
It was rescued by the one behind,
And if in error he was caught,
He had a saving afterthought
As he thought twice before he spoke,
He had no judgment to revoke,
And he could think without congestion
Upon both sides of any question
O gaze upon this model beast—
Defunct ten million years at least

THE WAR AND DRUG SUPPLIES

The Netherlands, the *Netherland colonies*, and Belgium are important sources of drugs used in all countries, the supply of which is now cut off or reduced. The most important drug to be affected is quinine, for its world market is controlled from Amsterdam and more than 95 per cent of the cinchona bark used in its production comes from the Netherland island of Java. Fortunately it seems that ample reserves of the alkaloid are in the military stores of the Allies and sufficient for civilian needs are warehoused in England, says a London letter in the *J A M A*. The market for caffeine and theobromine is also dominated by Netherland production, the former is extracted from tea and coffee waste and the latter from cocoa husk. A byproduct of the manufacture of cocoa, cacao butter, is also an important commodity of Netherland commerce. So also are the oils of caraway seed and nutmeg and gum benzoin, of which the tree *Styrax benzoin* grows in Sumatra. The best variety of aloes is produced in Netherland islands.

In Belgium many vegetable drugs, such as valerian and dandelion roots, marshmallow, and henbane, are cultivated. Now of course this source also is affected.

THE ROOT OF WISDOM

"To know when one does not know is best
To think one knows when one does not know is a dire disease.

Only he who recognizes this disease as a disease
Can cure himself of the disease
The Sage's way of curing disease
Also consists in making people recognize their diseases as diseases and thus ceasing to be diseased"—*Tao Te Ching*, quoted in *Current Medical Digest*

MEDICINE CAN NEVER BE A TRADE

"Charity is the eminent virtue of the medical profession. Show me the garret or the cellar which its messengers do not penetrate, tell me of the pestilence which its heroes have not braved in their errands of mercy, name to me the practitioner who is not ready to be the servant of servants in the case of humanity and whose footsteps you will find in the path of every haunt of stricken humanity"—*Oliver Wendell Holmes*

SUBACUTE BACTERIAL ENDOCARDITIS

Treatment with Sulfapyridine and Intravenous Injections of Typhoparatyphoid Vaccine

HARRY A. SOLOMON, M D, New York City

IN THE light of clinical experience it is evident that the treatment of subacute bacterial endocarditis with the sulfonamides alone has been disappointing.^{1,2,3} The improvement in the general condition of the patient which often follows the administration of the drug is of short duration, and in those cases that have recovered following this chemotherapy (an infrequent but nevertheless significant occurrence) the infection was mild or the treatment was instituted early in the course of the disease.^{4,5} That a condition in which the nidus of bacterial infection is protected from the influence of the circulating blood by a fibrin-platelet capsule favorable to bacterial growth should prove resistant to any form of chemotherapy is quite understandable. To overcome this difficulty of a protective barrier around the bacterial nidus, a method of therapy that combines heparin and sulfapyridine has been recommended.⁶

Since the excellent report of White and Parker⁷ wherein by a series of noteworthy experiments it was conclusively demonstrated that *in vitro* at temperatures above 39 C for three hours or longer the effect of sulfanilamide on various strains of hemolytic streptococci changed from inhibition to sterilization, we employed combined sulfonamide chemotherapy with protein shock therapy produced by the injection intravenously of typhoparatyphoid vaccine with gratifying results. Persistent cases of infectious arthritis, suppurative bronchitis and pneumonitis, etc., which did not respond to either chemotherapy or intravenous injections of typhoparatyphoid vaccine alone, promptly cleared when the two methods of treatment were used together. The purpose of this communication is to make a preliminary report of the results obtained in 8 cases of subacute bacterial endocarditis treated by this combined method of therapy.

Case Reports

Case 1—N L. was admitted to the Medical Service of Beth David Hospital, Dr. Louis

Presented at the meeting of the Beth David Hospital Clinical Society May 20 1940
From the Medical Service and Laboratories of Beth David Hospital. Consulting physician U. S. Marine Hospital, Stapleton, Staten Island

Hauswirth, Director, on November 22, 1938.

Two weeks before admission she had developed a "grippe" infection with fever, nausea, vomiting, headache, anorexia, and fleeting pains in the joints. Ten days before admission she had had a severe chill followed by high fever, which had persisted, together with severe pains in back of the head, lower spine, and chest, as well as shortness of breath and marked weakness.

At the age of 9 she had had chorea, and at the age of 12 she had been bedfast with rheumatic fever for five months.

The patient was a 19-year-old white girl appearing acutely ill with fever and slight dyspnea and cyanosis. There was a petechial hemorrhage in the right lower conjunctival sac. Over her back, arms, and chest anteriorly, crops of small petechiae were noted. The pharynx was congested, the teeth were in good condition, and the lungs were clear.

The heart was slightly enlarged to the left. A presystolic thrill and double murmur were present over the mitral area. The pulmonic second was accentuated, the rhythm, regular.

The edge of the liver was two fingers breadth below the costal margin and that of the spleen palpable one finger breadth below the ribs. Painful, discolored, indurated spots were present on the distal pads of several fingers and one toe. There was no edema or neuro-organic signs.

Laboratory Data—The temperature was 101 F, pulse, 100, respiratory rate, 20, blood pressure, 110/75. An analysis of the urine showed a trace of albumin, 3-5 red blood cells per high power field, and specific gravity 1.010. An analysis of the blood showed a hemoglobin of 80 per cent, red blood cells, 4,200,000, white blood cells, 27,800, polymorphonuclears, 75 per cent, lymphocytes, 23 per cent, monocytes, 2 per cent. Urea nitrogen was 16 mg, creatinine was 1.6 mg, and blood sugar was 155 mg. The blood culture showed many colonies of *Streptococcus viridans*.

The clinical picture of *Str. viridans* endocarditis engrafted upon rheumatic heart disease was probably of less than three weeks' duration. The temperature continued to spike to 103 F until sulfanilamide was started on the fourth day of admission when it remained around 100 F. On the sixth day of admission an intravenous injection of 0.5 minims of typhoparatyphoid vaccine was given which produced a rise in temperature to 104.5 F for several hours. Similar injections of the vaccine were given on the two subsequent days, after which the vaccine was stopped for two days but the sulfanilamide

continued Two more injections of vaccine were given, but the sulfanilamide was continued for a total of two weeks in doses of 1 Gm every four hours

All signs of infection subsided following the week of combined chemotherapy and foreign protein therapy The anemia increased during the two weeks of active treatment but improved rapidly with the discontinuance of sulfanilamide and the help of transfusions Repeated blood cultures have all been sterile The patient has been repeatedly examined and found to be free from any indication of active endocarditis, bacterial or otherwise There are no signs of a "bacteria-free" stage of subacute bacterial endocarditis, and her general condition has been consistently normal now for over one and a half years

Case 2—J M, a 40-year-old white unemployed ambulance driver, was admitted to the Medical Service of Beth David Hospital on February 7, 1939, complaining of shortness of breath, fever, sweats, weight loss, and weakness of two months' duration Two weeks before admission many large joints had become tender, and one day before admission he had suddenly developed weakness of the right arm and leg and difficulty in speech

At the age of 10 he had suffered from rheumatic fever, and between the years of 1919 and 1934 he had been bedridden on several occasions with polyarthritis for from three to six months at a time Since 1934 he had noticed dyspnea and palpitation on exertion

The patient presented the wasted, toxic appearance of chronic sepsis There were several petechiae in both lower conjunctival fornices, and the sclera was slightly icteroid The heart was enlarged to the left Double aortic and double mitral murmurs were present A few moist rales were heard over the right infra-scapular region The liver edge was two fingers breadth below the costal margin, and the rounded edge of a firm spleen was easily palpable Besides a few scattered petechiae on the arms there was a splinter hemorrhage beneath the nail of the fourth finger of the right hand Clubbing of the fingers was also noted

Laboratory Data—The temperature was 103.8 F, pulse, 110, respiratory rate, 24, blood pressure, 140/80 A urine analysis showed a trace of albumin, moderate white blood cells, occasional red blood cells, and specific gravity 1.024 The blood count showed a hemoglobin of 11.8 Gm, red blood cells, 4,100,000, white blood cells, 16,900, polymorphonuclears, 90 per cent (30 per cent nonsegmented), lymphocytes, 10 per cent The urea nitrogen was 11.7 mg, the creatinine 1.3 mg, the uric acid, 3.1 mg, icterus index 3.1 The blood culture was positive in forty-eight hours and showed eight colonies per cubic centimeter, gram-positive cocci in short chains, and nonhemolytic streptococci

Sulfanilamide therapy was instituted on the

fifth day of admission, starting with 2 Gm every four hours for six doses and afterward 1 Gm every four hours After twenty-four hours of sulfanilamide therapy, intravenous triple typhoid vaccine was given every evening for seven days The temperature was maintained over 105 F for three hours or longer with each daily course of protein shock therapy and usually returned to normal during the rest of the day Chemotherapy was stopped after ten days of uninterrupted administration

The general well-being of the patient improved rapidly, all signs of infection subsided, weight increased, and the patient left the hospital apparently well on March 21, 1939, after four weeks of normal temperature

Case 3—J C, a 27-year-old single white girl, beautician by occupation, entered Beth David Hospital on October 7, 1939 Shortly after the extraction of several teeth in April, 1939, she had noticed increasing weakness, anorexia, chills, sweats, and loss of weight Six weeks before she had been operated upon for appendicitis She had continued to grow weaker, various joints became painful without swelling, and during the past two weeks there had been episodes of sharp pain in the left lower chest. Of significance in the past history was an attack of "rheumatism" in childhood

The patient appeared very ill, toxic, and pale Two elliptic hemorrhages with white centers were present in the retina of the left eye The heart was enlarged to the left, the apex being outside the midclavicular line in the fifth intercostal space A systolic murmur transmitted to the axilla was present over the mitral area Over the aortic valve area there was a rough systolic murmur and a soft diastolic murmur The liver was enlarged two fingers breadth downward, and the edge of the spleen was felt at the costal margin on inspiration

Laboratory Data—The temperature was 104.6, pulse, 116, respiratory rate, 24, blood pressure, 110/80 An analysis of the urine revealed a few white blood cells and specific gravity 1.014 The blood count showed a hemoglobin of 49 per cent, red blood cells, 2,480,000, white blood cells, 8,700, polymorphonuclears, 70 per cent (16 per cent nonsegmented) Three daily blood cultures were positive for *Str. viridans* averaging over twenty colonies per cubic centimeter of blood

After six days, during which time the signs of infection were essentially unchanged, sulfapyridine was administered, first in 2-Gm doses every four hours for one day and then a 1-Gm dose every four hours The temperature remained normal under chemotherapy for forty-eight hours, and on the third day triple typhoid vaccine therapy was instituted By this means the temperature was kept elevated from 105 to 106 F for three hours every night for seven paroxysms, and then both chemotherapy and protein shock therapy were discontinued

The sulfapyridine concentration of the blood varied from 12.5 to 4 mg per hundred cubic centimeters. The white blood count averaged 18,000 for the first five days of treatment, but on the tenth day the white count dropped to 2,000. Following discontinuation of the combined treatment, the general condition of the patient was strikingly improved, the temperature remained normal, and repeated blood cultures were sterile. The patient left the hospital four weeks after admission in what appeared to be excellent health.

She was readmitted one week later seriously ill with agranulocytosis. She had received sulfanilamide at home for a sore throat which she presumably contracted from a member of her family. She died three days after her second admission of agranulocytosis, but intensive clinical and bacteriologic study revealed no evidence of the original infection. Permission for an autopsy could not be obtained.

Case 4—N. R., a 41-year-old dentist, was referred to Beth David Hospital by Dr. George Cole on August 31, 1939. About six months prior to admission he had noticed increasing difficulty in carrying on his work because of weakness, listlessness, and fleeting joint pains and, since an attack of "grippe" one month later, he was practically bedridden. The "rheumatic pains" had increased, weakness had become more marked, bouts of fever had been frequent, and weight loss had progressed. About two weeks before admission, difficulty in speech had developed suddenly. There was no history of rheumatic fever. Seventeen years ago he had had a "breakdown due to overwork." He had had a number of gallbladder attacks, and there had been x-ray evidence of calculi in the gallbladder. Left-sided calculous pyelonephritis with hypertension had also been known to be present for the past four years. The tonsils had been removed three years before because of recurrent sore throat episodes.

The general appearance was that of an adult white man with a very sallow complexion, apathetic, toxic, and emaciated. Slight dysarthria and weakness of the lower part of right side of the face was present. Petechial hemorrhages were present in the folds of both lower conjunctival sacs, and Roth spots were present in both retinas. The teeth were in good condition and the lung signs were normal. A few scattered petechiae were present over the upper part of the chest.

The heart was rapid and regular. The apex beat was in the sixth space outside the mid-clavicular line. A loud systolic blowing murmur over the mitral area replaced the first sound and was transmitted to the left.

The abdomen was normal except for the spleen which was just palpable on deep inspiration.

Laboratory Data—The temperature was 101.4 F., pulse, 100, respiratory rate, 20, blood pressure, 95/80. A urine analysis showed a

2 plus albumin, a few red and white blood cells, and specific gravity 1.018. The blood count showed a hemoglobin of 51 per cent, red blood cells, 2,710,000, white blood cells, 6,600, polymorphonuclears, 88 per cent (40 per cent non-segmented), lymphocytes, 10 per cent, monocytes, 2 per cent. The blood cultures were positive for *Str. viridans* on many occasions before admission.

The clinical picture was that of subacute bacterial endocarditis due to *Str. viridans* with at least five months of a severe septic state and serious embolization.

Treatment was begun on the day after admission by giving 2 Gm. of sulfapyridine every four hours for six doses and then 1 Gm. every four hours thereafter. Thirty-six hours after chemotherapy was started, triple typhoid vaccine was administered intravenously each night for a series of six injections, after which all treatment was stopped because of uncontrollable vomiting. The sulfapyridine concentration of the blood varied from 1.7 to 7 mg per hundred cubic centimeters. The white blood count averaged about 11,000 during the treatment.

For one week after the combined therapy was stopped, the temperature was normal and the general condition of the patient was improved. Signs of infection, however, reappeared but with less severity. Another course of similar therapy for five days was tried one month after the first one, but the control of the general infection was again only of short duration. The patient died of cerebral hemorrhage on December 1, 1939.

An autopsy performed by Dr. Milton Helpert, pathologist of Beth David Hospital, revealed that the vegetations on the mitral valve and endocardium were very extensive and plastered down in a thin, firm, flattened layer.

Case 5—A. P., a 19-year-old Italian girl, was referred to Beth David Hospital by Dr. Morris Oken on January 25, 1940. Four weeks before admission she had developed a "grippe" infection as manifested by chills, irregular fever, general aches, and prostration. Sulfanilamide therapy had been tried during the first week of illness, but it did not influence the fever or improve the general condition. The septic state had continued in a severe form. Two days before admission the blood culture was reported positive for *Str. viridans*. Sulfapyridine had been administered for two days at home before the patient was transferred to the hospital.

At the age of 10 the patient had been bedfast for four months with rheumatic polyarthritis and carditis. Despite several operations for removal of tonsils she suffered from frequent throat infections.

The patient appeared acutely ill, poorly nourished, dehydrated, extremely toxic, and pale. There was a fresh petechial hemorrhage in the left conjunctival fold and several painful Osler nodes in the pads of several finger tips and both heels. The teeth and gums were in excellent

condition The pulsations of the neck were prominent and rapid The heart was enlarged downward, and a systolic murmur over the mitral area and a double murmur over the aortic area were present The lungs were clear The edge of the spleen extended one inch below the costal margin

Laboratory Data—The temperature was 100.8 F, pulse, 108, respiratory rate, 24, blood pressure, 136/60 Urine analysis showed a trace of albumin, a few white blood cells, and specific gravity 1.019 The blood count showed 3,680,000 red blood cells, white blood cells, 13,800, polymorphonuclears, 80 per cent (nonsegmented 18%), lymphocytes, 18 per cent, monocytes, 2 per cent Sulfapyridine concentration of the blood was 6 mg per hundred cubic centimeters

The patient presented all the clinical and bacteriologic criteria for a diagnosis of subacute bacterial endocarditis due to *Str viridans*. Because she received adequate doses of sulfapyridine for several days before admission, the drug was continued at 1 Gm every four hours, and the intravenous triple typhoid vaccine series was started on the night of the day of admission to the hospital Seven nightly typhoid vaccine series were given, the temperature being maintained from 104.5 to 106 F for over three hours at a time daily Sulfapyridine was continued for only one day after the typhoid vaccine was stopped because of the development of mental symptoms due no doubt to the sulfapyridine In this case sulfapyridine was given for ten days with the concentration of the drug in the blood averaging around 6 mg per hundred cubic centimeters The daily white blood count varied from 30,000 to 16,000, and the polymorphonuclear cells averaged 85 per cent

Since discontinuation of the treatment on the tenth hospital day, the patient has been free from any signs or symptoms of infection Repeated blood cultures are normal, temperature is not elevated, the urine is free from any indication of renal damage, there is no anemia, and her general condition is excellent

Case 6—L O, a 22-year-old white man, was referred by Dr Julius Tannenbaum and admitted to the Doctors Hospital, March 14, 1940

His present illness had begun about four months before admission, with malaise, irregular fever, pain and swelling of the joints, and progressive loss of weight He had been in failing health manifested by weakness, loss of weight, anorexia, fleeting joint pains for five months Two months before admission he had developed chills, high fever, drenching sweats, vomiting, and severe pains over spleen and kidney regions He was known to have had a heart murmur since infancy and a duodenal ulcer for the past five years

He had the appearance of a well-developed young man who showed the effects of chronic sepsis—viz, cachexia, pallor, toxemia, and

listlessness Characteristic embolic phenomena were present in large numbers in the retinas and skin, especially in the palms of the hands, soles of the feet, and around the ankles The teeth and gums were well kept

The heart was enlarged transversely Over the base of the heart a loud rough systolic murmur was heard over a wide area An aortic diastolic murmur was also present The lungs were clear The spleen extended two fingers below the costal margin, and its firm rounded edge was tender

The right ankle was swollen, tender, and ecchymotic, the right posterior tibial pulsation was absent There was marked clubbing of the fingers There were no neuro-organic signs

Laboratory Data—The temperature was 105 F, pulse, 126, respiratory rate, 28, blood pressure, 140/40 Urine analysis showed a 2 plus albumin, many red and white blood cells, and specific gravity 1.016 The blood culture showed over twenty-five colonies of *Str viridans* per cubic centimeter of blood

This severe and long standing case of *Str viridans* endocarditis was probably engrafted upon a congenital type of heart disease with an interventricular septum defect

Treatment was instituted as in the previous cases with sulfapyridine, and one day later intravenous triple typhoid vaccine injections were started Only six series of vaccine injections could be given because of uncontrollable vomiting and hematemesis

For eight days after the continued therapy was stopped the temperature remained normal, and the general condition of the patient improved greatly Later, however, signs of infection reappeared, and it became evident both clinically and bacteriologically that the infection had recurred, although on a lower level of activity

Case 7—E S, a 14-year-old white school boy, was referred to the Medical Service of Beth David Hospital by Dr Harry Sherman on March 20, 1940, and discharged May 4, 1940 Three and one-half weeks before admission he had developed a sore throat, high fever, marked weakness, and palpitation After a few days the symptoms had appeared to diminish only to recur with increased intensity

He had had measles and pertussis in infancy At six years of age he had developed scarlet fever which had been followed by acute nephritis with generalized edema and smoky urine These had subsequently cleared entirely He suffered frequent colds and sore throats Five separate operations for diseased recurrent tonsils had been performed, and a left mastoidectomy had been necessary at four years of age

He was a well-developed but thin boy who appeared acutely ill, pale, and septic Pulsations of the neck and precordium were markedly exaggerated Petechial hemorrhages were noted on the palate and floor of the mouth as well as in

crops over both shoulders, chest, and arms. The teeth were not infected.

The heart was enlarged to the left and its rhythm regular. A soft systolic murmur over the apex was transmitted to the axilla, and a low pitched diastolic murmur over the aortic area was transmitted downward. The lungs were clear, the liver edge was palpable, and the spleen was suspiciously palpable at the costal margin. There were a few painful red areas on the toes and heels.

Laboratory Data—The temperature was 104 F, pulse, 100, respiratory rate, 24, blood pressure, 135/25. Urine analysis showed a faint trace of albumin, few red and white blood cells, and specific gravity 1.012. The blood count showed a hemoglobin of 7.6 Gm, red blood cells 2,400,000, white blood cells, 15,000, polymorphonuclears, 70 per cent (8 per cent nonsegmented), lymphocytes, 26 per cent, monocytes, 4 per cent. Urea nitrogen was 17 mg, creatinine, 1.6 mg, blood sugar, 110 mg. The blood culture was positive after twenty-four hours' incubation and revealed fifteen colonies of *Str. viridans*.

The rather severe manifestations of bacterial endocarditis due to *Str. viridans* were of about one month's duration before treatment was instituted. Six grams of sulfapyridine were administered per os during the twenty-four hours before triple typhoid vaccine was injected intravenously. Temperature over 105 F for three hours was maintained once every night for eight nights. On the tenth day after admission both chemotherapy and typhoid vaccine injections were discontinued because the white count, which varied between 24,000 and 31,000, dropped to 3,200 on the ninth day of treatment. The sulfapyridine concentration varied between 10 to 2.8 mg per hundred cubic centimeters.

After treatment was stopped blood cultures taken every three days were all negative. His temperature, blood count, urine, and general condition remain normal to date.

Case 8—B. S. entered Beth David Hospital on April 4, 1940, and was discharged May 17, 1940. His present illness had begun six weeks before admission with chilliness, irregular fever to 104 F, pains in back and legs, headache, and malaise. He had been treated at home by his private physician for over three weeks, having received 10 Gm of sulfapyridine during part of the last week of this period. He had been admitted to the Bronx Hospital, New York City, on March 18, 1940, where he had remained for seventeen days. Here his condition had been diagnosed as subacute bacterial endocarditis due to *Str. viridans* as evidenced by a severe septic state, rheumatic heart disease with aortic insufficiency, embolic phenomena, splenomegaly, and positive blood cultures. Sulfanilamide had been given during his stay at this institution without any influence on the infectious state.

Aside from a history of scarlet fever at 9 years of age, the past history was entirely negative.

On examination at Beth David Hospital this 37-year-old white man was extremely septic, wasted, and exhausted. The scleras were distinctly icteric. The teeth were discolored and loose, and the gums were swollen and exuding pus. The heart was enlarged to the sixth intercostal space. A short systolic and a soft low-pitched diastolic murmur were present over the aortic area. The lungs gave no abnormal signs.

The liver was diffusely enlarged almost to the umbilicus, tender, and surface smooth. The edge of the spleen was felt about two inches below the costal margin. There was a splinter hemorrhage under the nail of the right fourth finger, and several discolored painful nodes were present over both insteps and heels.

Laboratory Data—The temperature was 103.8 F, pulse, 112, respiratory rate, 22, blood pressure, 110/60. Urine analysis showed a trace of albumin, a few red blood cells, moderate white blood cells, and specific gravity 1.018. The blood count showed a hemoglobin of 9.8 Gm, red blood cells, 3,750,000, white blood cells, 13,350, polymorphonuclears, 80 per cent (12 per cent nonsegmented), lymphocytes, 14 per cent, monocytes, 4 per cent, myelocytes, 2 per cent, reticulocytes, 1 per cent. Urea nitrogen was 12 mg, creatinine, 1.5 mg, uric acid, 3 mg, blood sugar, 120 mg, icterus index 30.

A severe toxic hepatitis, probably due to the chemotherapy, complicated this rather severe case of subacute bacterial endocarditis. Nevertheless, the combined treatment of sulfapyridine and intravenous triple typhoid vaccine was instituted in the usual manner, reinforced by infusions of hypertonic glucose and normal saline solutions. Ten nightly series of vaccine were given over a period of eleven days with three-hour periods of fever ranging from 105 to 107.2 F. Chemotherapy was continued for one week after the vaccine was stopped. Sulfapyridine concentration of the blood varied from 8.8 to 5 mg per hundred cubic centimeters. The white cells varied from 27,000 during the first week of treatment to 9,800 during the second week of treatment.

Blood cultures taken every three days during and following treatment were all sterile. With cessation of the combined treatment the fever remained normal and the general condition improved strikingly. The patient gained over 30 pounds when he left the hospital and has remained in excellent condition.

Comment

The use of typhoparathyphoid vaccine by intravenous injection has been universally known as a valuable form of treatment in certain resistant forms of infection. It is a safe, economical, and simple method of therapy. Its effectiveness probably depends on

the production of a "shock" reaction, artificial fever, increased circulatory flow with vasodilation, stimulation of cellular (reticulo-endothelial) and glandular activity, increased polymorphonuclear leukocytosis with decreased lymphocytosis, as well as stimulation of other factors in the mechanism of immunity.⁸

The sulfonamide group of drugs has, in general, failed as effective therapeutic agents against the infections causing subacute bacterial endocarditis. The mode of action of this form of chemotherapy, while not completely known, is clearly one of bacteriostasis with little or no bactericidal effect.

By combining foreign protein shock therapy with the sulfonamides, the effectiveness of the drug is enhanced not only by the hyperpyrexia produced, which in itself renders the drug bactericidal instead of bacteriostatic, but also by the addition of many factors in immunity, some not clearly understood, which are activated at the same time.

The results obtained by this combined method of therapy in 8 cases of subacute bacterial endocarditis, 7 of which were due to *Str. viridans* and 1 to nonhemolytic streptococcus during the past twenty-one months, has been extremely encouraging. The cases presented adequate criteria for a diagnosis of active bacterial endocarditis including at least one positive blood culture in each case. Five of the cases are well, 1 for eighteen months, 1 for fifteen months, 1 for three months, and 2 for over two months. One patient died of agranulocytosis one month after leaving the hospital but showed no clinical or bacteriologic evidence of a recurrence of the original infection. In 2 cases the treatment failed, although a temporary improvement in the general condition did occur. In one of these unsuccessful cases the infection existed over four months and was probably superimposed on congenital defect of the interventricular septum. In the second unsuccessful case the disease existed over six months and at autopsy showed firm, flat vegetations plastered extensively over the endocardium. As both of these cases had received a great deal of sulfonamide chemotherapy for a long time before the combined form of treatment was instituted, the question of bacterial resistance to the therapeutic agent is suggested. However, Case 8 is illustrative of the fact that the combined therapy may still prove effective even after prolonged sulfonamide therapy alone has failed.

The method of therapy was as follows: sulfapyridine in 2-Gm doses every four hours was given for two doses and then reduced to 1 Gm every four hours. On the night of the second day of sulfapyridine therapy an intravenous injection of 1/2 minim of typhoparatyphoid vaccine was given, and the same dose was repeated in one or two hours if necessary in order to maintain the temperature above 104 F for at least three hours continuously. The vaccine was continued each night for from seven to ten days, the amount of vaccine being increased as required to produce the designated degree and duration of the hyperpyrexia. The injections were given several hours after the last meal of the day so that the reaction of the shock therapy should not interfere with the intake of nourishment. Accessory measures, such as infusions, transfusions, high caloric diet, extra salt and vitamins, sedatives, etc., were all utilized as indicated. Of course, adequate blood and urine examinations to follow the concentration of the drug in the blood and to discover early evidence of toxic effects were carried out routinely. Sulfapyridine was usually given for a week or less after the vaccine therapy was discontinued.

Summary

In a series of 8 cases of subacute bacterial endocarditis, the results obtained with a method of therapy that employs intravenous injections of typhoparatyphoid vaccine as an adjuvant to sulfapyridine therapy have been favorable. In submitting this preliminary report of a new method of treatment for subacute bacterial endocarditis, the necessity for early recognition and prompt treatment of the disease cannot be too strongly emphasized.

BUROW'S SOLUTION

A New Method of Preparing Liquor Aluminum Acetate (N F)

F C COMBES, M D , New York City

IN A recent review¹ dealing with the value of Burow's solution in diseases of the integument, the several deficiencies of the National Formulary preparation were reviewed. These objectionable features may be briefly stated as follows:

1 Excess lead in the filtrate According to the *National Formulary*,² liquor aluminum acetate is prepared as follows:

Lead acetate	150 Gm
Aluminum sulfate	87 Gm
Water sufficient to make	1,000 cc

The author has previously shown that on a basis of molecular weights, when 150 Gm of lead acetate are used, the amount of aluminum sulfate necessary to precipitate all the lead and achieve molecular equilibrium is 87.84 Gm. If only 87 Gm are used as specified, there is an excess of lead acetate in the finished solution amounting to 1.45 Gm. This is equivalent to 0.079 Gm of lead per hundred cubic centimeters. Routine examinations of samples prepared and dispensed by various pharmacists have shown these figures to be as high as 0.240 Gm per hundred cubic centimeters.

The National Formulary Committee has never specified any restrictions on the lead content. However, the present committee has ruled that, in the future, solutions must pass the following test which will detect lead in amounts in excess of 0.04 Gm per hundred cubic centimeters. One cubic centimeter of dilute sulfuric acid is added to 5 cc of liquor aluminum acetate. There should be no visible precipitate.

To achieve this it is not unreasonable to assume that the pharmacist or manufacturer will add an excess of aluminum sulfate resulting in free sulfates for which there is no assay requirement and which, from a therapeutic standpoint, are as objectionable as the lead.

2 Variations in the hydrogen-ion concentration. Routine tests done on eighteen lots purchased in the market showed variations between pH 3.70 and 4.45.

3 Variations in aluminum acetate content.

From the Department of Dermatology, New York University College of Medicine and the Dermatological Service of the Third (New York University) Medical Division, Bellevue Hospital.

Similar tests showed variations between 4.5 and 5.9 per cent.

4 Lack of stability resulting in precipitation of basic aluminum acetate associated with a decrease in acidity of the solution and in the aluminum acetate content.

5 Frequent irritation of the skin, which is in part responsible for the hesitancy of many physicians to use the National Formulary preparation.

Karl August von Burow proposed the original formula with directions for its preparation as follows:

1	Lead acetate (crystalline)	100 Gm
	Distilled water	300 Gm
2	Alumen	66 Gm
	Sodium sulfate	12 Gm
	Distilled water	500 Gm

The two solutions should be mixed cold, allowed to stand for two days at a temperature of 10 C, and then filtered without washing the precipitate.

Numerous changes have been made in the National Formulary preparation since Burow's solution was first included, but, notwithstanding the superiority of the present preparation, it still does not conform to the requisite that should be demanded of such a valuable medication. The *Deutsches Arznei-Buch*, which in Germany corresponds to our pharmacopoeia, cognizant many years ago of its objectionable features, introduced a substitute for the original Burow's solution in "Essigsäure Tonerde." Sulzberger³ has said that he "discovered our Burow's solution was often if not inferior in action to the Essigsäure Tonerde, at least much more uncertain and irregular in its effects." It is a reflection on the pharmaceutical profession in this country that many pharmacists in small towns and villages have never heard of Burow's solution, and how often difficulty is encountered in finding a pharmacist who has any available for dispensing purposes. Furthermore, every drug clerk seems to have his own method of preparation.

In search for a solution of aluminum acetate which would be standard, stable, and at the same time free of the objectionable features which stigmatize the National Formulary preparation, the author has examined and

tried several modifications prepared by different methods, including the addition of various stabilizers. A satisfactory solution seems to have been found in one that is prepared without lead and in which boron is added as a stabilizer.

There is no assay requirement for lead and sulfates in the National Formulary preparation. This fact made it necessary to decide upon a certain hypothetical set of standards before attempting to prepare a solution, basically the same. These standards follow:

- 1 It should contain no lead
- 2 Aluminum sulfate should be kept to a minimum
- 3 It should be standard as regards hydrogen-ion concentration and aluminum acetate content
- 4 It should be nonirritating and capable of exerting a buffer action equal or superior to that exhibited by liquor aluminum acetate (N F)
- 5 It should show a minimum amount of precipitation on standing
- 6 If precipitation occurs, it should not appreciably affect the pH or the aluminum acetate content
- 7 It should conform to the National Formulary requirements with regard to its aluminum acetate content

The solution that fills practically all these requirements has been given an extensive clinical trial and has been found equal if not superior to the National Formulary solution in its effects on the skin. The "New Burow's Solution" can be prepared by the manufac-

turer from a stable base that is not made by the precipitation method.

Physicochemical Properties—For comparative purposes the new Burow's solution was compared with bulk liquor aluminum acetate (N F) as prepared by three manufacturing chemists (see Table 1).

It will be noted that the physicochemical properties of the new Burow's solution compare favorably with the official solutions. It has the added advantage that no lead is used in its preparation, so that the finished product is free of lead and sulfates except in amounts estimated as less than traces.

Buffer Action—One of the major properties of liquor Burowi is its ease of dissociation and its ability to remain in a state of continuous ionization, thus rendering it capable of correcting variations in the pH values of the skin. Comparative tests of this buffer action to equal volumes of standard solutions were made (see Table 2).

It may be seen from this table that the undiluted solution shows the same maximum variation as the National Formulary solution but that the new Burow's solution, diluted with ten volumes of water, shows a maximum variation of pH 1.3 less than the National Formulary solution. Its buffer qualities are, therefore, far superior to this preparation.

Stability—One disadvantage of all aluminum acetate solutions is precipitation on standing. This begins at normal temperatures in from two to three months. This precipitate consists of basic aluminum acetate and is associated with a corresponding de-

TABLE 3—VARIATIONS IN ALUMINUM ACETATE CONTENT OVER A PERIOD OF APPROXIMATELY TEN WEEKS

	May 4, 1940	July 22 1940
Percentage Al_2O_3	1 37%	1 34%
Total caustic soda titration as acetic acid	4 84%	4 78%
pH value	3 9	4 0
pH value diluted to 10 per cent with water	4 2	4 2
Aluminum acetate	5 4%	5 3%

crease in potential acidity. Several samples have shown variations over a three-month period ranging up to pH 1. The new Burow's solution showed a variation of 0.1, decreasing from pH 3.9 to 4.0. In addition there was no appreciable change in the aluminum acetate content or in its buffer action (see Tables 3 and 4).

Clinical Tests and the Reaction of Normal Skin—Fifty-two subjects were patch tested with the solution diluted with ten volumes of water with no reaction after forty-eight hours.

Twenty-five subjects were patch tested with the solution undiluted. None showed any reaction after forty-eight hours.

Effect on Inflamed Skin—Fifty patients presenting various dermatologic and surgical conditions were treated with the solution as a wet compress. It was found that the best results followed the use of dilutions of 1-20 with water. Within certain limits dilution increases the buffer action and does not appreciably disturb the hydrogen-ion concentration. Conditions responding favorably included the following: dermatitis venenata (contact dermatitis due to various mechanical, thermal, chemical, and plant irritants), urticaria, cellulitis, insect bites, cutaneous abrasions, abscesses and carbuncles, ecthyma, pompholyx, acute dermatophytosis, vesicular and bullous microbids, paronychia

The dilutions were made to 10 per cent with distilled water.

The buffering action with alkalis and acids is shown by the pH values of equal volumes of test solutions and alkalis and acids.

(acute), erysipelas, balanitis and chancroid, lymphangitis, syccosis vulgaris, suppurating lymphadenitis, and conjunctivitis.

In many instances it was possible to compare the new Burow's with the official solution by applying them, respectively, to different portions of the inflamed integument on the same subject, i.e., either leg or either hand. There was no visible subjective or objective difference in their effect, although several patients volunteered that the new solution felt more comfortable.

Summary

A new Burow's solution is recommended which conforms to the assay requirements of the *National Formulary*. It is superior to the old preparation in many of its clinical and therapeutic properties, especially in that it contains no free lead and only a faint trace of sulfates and is superior as a buffer solution. For therapy it is diluted 1-20 or more with water.

HELPFUL BOOKLET ON GONORRHEA

The United States Public Health Service is distributing a new booklet entitled "20 Questions on Gonorrhea." It was developed with the active assistance of officers and members of the Neusserian Medical Society, is written in layman's language, and will be valuable to the physician who wants to know how to tell the story of

gonorrhea in nontechnical terms. It could be a valuable aid to the physician to give to his patients. The booklet is illustrated with schematic anatomic drawings and is available from the Superintendent of Documents, Washington, D. C., for five cents per copy and with a 25 per cent reduction on orders of 100 or more.

SOMEBODY QUITE DIFFERENT

Dr. Hugh Cabot would have us plunge into group practice, divided responsibilities, buck passing, and all, because we are such an immoral group of individuals without principle or high

standards! Boston still may be the home of the bean and the cod, but the Cabots no longer show evidence of talking only with God.—*J. Connecticut Med. Soc.*

tried several modifications prepared by different methods, including the addition of various stabilizers. A satisfactory solution seems to have been found in one that is prepared without lead and in which boron is added as a stabilizer.

There is no assay requirement for lead and sulfates in the National Formulary preparation. This fact made it necessary to decide upon a certain hypothetical set of standards before attempting to prepare a solution, basically the same. These standards follow:

- 1 It should contain no lead
- 2 Aluminum sulfate should be kept to a minimum
- 3 It should be standard as regards hydrogen-ion concentration and aluminum acetate content
- 4 It should be nonirritating and capable of exerting a buffer action equal or superior to that exhibited by liquor aluminum acetate (N F)
- 5 It should show a minimum amount of precipitation on standing
- 6 If precipitation occurs, it should not appreciably affect the pH or the aluminum acetate content
- 7 It should conform to the National Formulary requirements with regard to its aluminum acetate content

The solution that fills practically all these requirements has been given an extensive clinical trial and has been found equal if not superior to the National Formulary solution in its effects on the skin. The "New Burow's Solution" can be prepared by the manufac-

turer from a stable base that is not made by the precipitation method.

Physicochemical Properties—For comparative purposes the new Burow's solution was compared with bulk liquor aluminum acetate (N F) as prepared by three manufacturing chemists (see Table 1).

It will be noted that the physicochemical properties of the new Burow's solution compare favorably with the official solutions. It has the added advantage that no lead is used in its preparation, so that the finished product is free of lead and sulfates except in amounts estimated as less than traces.

Buffer Action—One of the major properties of liquor Burowi is its ease of dissociation and its ability to remain in a state of continuous ionization, thus rendering it capable of correcting variations in the pH values of the skin. Comparative tests of this buffer action to equal volumes of standard solutions were made (see Table 2).

It may be seen from this table that the undiluted solution shows the same maximum variation as the National Formulary solution but that the new Burow's solution, diluted with ten volumes of water, shows a maximum variation of pH 1.3 less than the National Formulary solution. Its buffer qualities are, therefore, far superior to this preparation.

Stability—One disadvantage of all aluminum acetate solutions is precipitation on standing. This begins at normal temperatures in from two to three months. This precipitate consists of basic aluminum acetate and is associated with a corresponding de-

of the liver, distention of the jugular veins, and increase in venous pressure suggest that congestive heart failure has occurred. In that case I think the treatment should be immediate and drastic, and it is our practice to use ouabain, intravenously, in a dose of 0.5 mg. at first and perhaps a dose of 0.3 mg. after four or six hours. Usually on the second and third day after the onset there is no need for further digitalization. If there is, give digitals by mouth in doses of usually six cat units the first day and then, depending upon the patient's condition, three cat units daily for the next few days.

In an analysis recently made of our first 100 patients with this disease, only 1 had acute cardiac decompensation. It does not, therefore, present a very frequent therapeutic problem.

Convulsive seizures, occasionally with coma, which sometimes occur at the onset of the disease, are probably due to increased intracranial pressure. It may be due to cerebral vascular spasm and edema of the brain. The treatment is important because many of the deaths, the sudden deaths, which occur in the acute stage of the disease are related to some encephalopathic manifestation—coma or repeated convulsive seizures. It is extremely difficult to evaluate therapy, because even these encephalopathic manifestations tend to correct themselves and they rarely continue longer than the first twenty-four or thirty-six hours after the onset. Magnesium sulfate, intravenously, appears to be of some value. It is our practice to give 4 cc. of a 50 per cent solution intravenously and repeat in two or three hours if the convulsive seizure recurs. When there is coma, spinal tap should be done. The coma also tends to correct itself, but one hesitates to allow it to continue. We have seen patients come out of coma very promptly after a slow drip spinal tap. Never do we allow the fluid to run out fast.

Anuria is another manifestation of the disease which calls for treatment. Anuria is not a common complication and, when it occurs, rarely lasts for more than forty-eight hours. Anuria that proves fatal is usually that type which develops later in the disease—that is, a recurrence in the second and third weeks. Anuria at the onset, however, is a short-lived process, accompanied usually by stupor, symptoms of uremia, and nitrogenous retention. It is an advantage to get the urine to flow, but I do not know of any treatment that insures that result.

Renal decapsulation has been suggested

It is now done much less frequently than it was fifteen or twenty years ago. Because the anuria tends to correct itself spontaneously, one is never certain that the operation has made the difference. Short-wave diathermy and other forms of local application of heat have been tried with results that are not convincing. Hypertonic infusions, sucrose and now perhaps mannitol and dulcitol, and 50 per cent glucose solutions have been tried and, it seems to me, without any rational background. If the mechanism of anuria is due to deficient blood flow through the glomeruli, which it probably is, it is hard to see how any kind of a solution, even a hypertonic solution, would correct that functional disturbance.

The occurrence of uremia in acute diffuse glomerulonephritis at its onset is not a serious manifestation as far as the outcome is concerned. Young patients with this disease in a stage in which there is fixation of the specific gravity of the urine and extremely high non-protein nitrogen in the blood make a complete recovery in about the same time as those in whom uremia is not an initial feature. The symptoms are sometimes alarming. Treatment is mostly empirical, with infusions of hypertonic solutions. Acidosis and dyspnea that may result from the retention of acid phosphate and other acid products may sometimes be corrected at least temporarily by the intravenous infusion of sodium bicarbonate and normal saline.

Among the less important symptoms is edema. I say less important because it does not matter very much in this disease whether one corrects the edema or not. I think it is more important to do what one can to prevent the edema from progressing. There is no diuretic mechanism with which I am familiar that will correct the edema of acute diffuse glomerulonephritis. Presumably this disease is a diffuse vascular inflammation in which the vascular system of the kidney is merely incidentally involved, and the edema most likely is due to the increased capillary permeability in the area injured by the hemolytic streptococcal toxin. Since we know of no means of reducing the permeability of capillaries under these conditions, no measures can be directed toward that mechanism. Restriction of sodium is of some value. There appears to be no necessity, from a physiologic point of view, for the limitation of fluids, since with restriction of sodium the fluids taken in are excreted. In fact, Volhard at one time suggested as the treatment for the edema the ingestion of 1,500 cc. of water, after

Therapeutics

CONFERENCES ON THERAPY

THE first of this series appeared in the December 1 issue. These are stenographic reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital, with collaboration of other departments and institutions. The questions and discussions involve participation by members of the staff of the college and hospital, students, and visitors. These conferences will appear in each issue published on the first of the month. The next report will concern "Treatment of Pneumonia."

The Management of Nephritis

DR EUGENE F DuBOIS. We are particularly fortunate in having as guests two men from the New York University College of Medicine. In our sister institution the Departments of Medicine and Physiology have been performing some of the most fundamental work in nephritis and the physiology of the kidney. The clinical aspects will first be discussed by Dr Goldring.

DR WILLIAM GOLDRING. My part of the discussion will have to do with the treatment of diffuse glomerulonephritis, that type of renal disease which has been defined as a bilateral nonsuppurative inflammation of the kidneys. The etiology of diffuse glomerulonephritis is still in doubt. There is some information leading to the supposition that an allergic response on the part of the renal tissue is the cause of the manifestations, particularly the fact that most occur in the convalescent period following an acute infection. There is also sufficient evidence that infection, that is, the nephrotoxin of the hemolytic streptococcus, is the cause. The hemolytic streptococcus is not the only organism associated with the disease, although it is the most frequent.

Acute diffuse glomerulonephritis is not a very serious disease because about 70 per cent recover completely. Only about 5 per cent die in the acute attack, and the remaining 25 per cent either become latent or pass into the chronic stage.

One of the principal difficulties that I have in discussing the treatment results from the fact that the etiology or the mechanism of the changes is unknown. For that reason the treatment is essentially symptomatic. It might be of use to distinguish the manifestations of the disease which threaten life and require immediate and prompt attention from those that are unimportant as far as treatment is concerned. Among the more important ones are acute left ventricular failure, conges-

tive heart failure, encephalopathy, anuria, and uremia, and among the less important are edema and hypertension without encephalopathy. I will consider these as well as certain general questions—such as, when the patient should be allowed out of bed, what to do about suspected foci of infection, and finally, diet.

Acute diffuse glomerulonephritis is most often a disease which sets in abruptly in the convalescent stage of an infectious disease. Paroxysmal dyspnea may mark the onset. This is probably the result of the sudden rise in blood pressure with strain on the left ventricle. There is some reason to believe that the diffuse vascular injury, which is part of this disease, affects the coronary vessels as well as the renal and other systemic vessels. The treatment of acute paroxysmal dyspnea as it occurs at the onset is not very important, since most patients recover from this without treatment. The acute phase of that manifestation rarely lasts for more than one day and exceptionally may go as long as four or five days. Morphine helps to tide them over. Venesection has been suggested in acute left ventricular failure when it occurs in persons with organic heart disease, because the removal of a volume of blood makes it easier for the left ventricle to adjust itself. However, I have never seen it used in the acute left ventricular failure of acute diffuse glomerulonephritis and I do not think it plays the same important role as it does in organic heart diseases.

Congestive heart failure occurring at the onset of an acute diffuse glomerulonephritis is a rare occurrence, probably due either to sudden increase in blood pressure or to capillary or vascular damage in the myocardium itself. Congestive heart failure may be difficult to recognize because edema is so often a part of the renal disease, but enlargement

something done. The usual course of events is the use of the high protein diet, perhaps in addition to thyroxin or thyroid by mouth to hasten the effect on plasma protein regeneration, but without avail. One must usually resort to the diuretics. In my experience the mercurial diuretics are by far the most effective. The diuretic effect is temporary, the edema almost invariably returns within a short time unless the diuretics are continued until the patient either recovers, which occasionally happens, or goes into the hypertensive stage where the edema disappears spontaneously. In such cases the fibrosis of the kidney with destruction of glomeruli results in a smaller loss of protein and a greater concentration in the blood. In time this leads to the spontaneous disappearance of the edema.

The use of a mercurial diuretic always calls for discussion because mercury compounds are known to be nephrotoxic. The statement is made—and I think fairly generally—that if a patient has any degree of renal insufficiency as judged, for example, by loss of concentrating power or if there is blood in the urine, even microscopic hematuria, the mercury diuretics are contraindicated. My own feeling is that the mercurial diuretic is not harmful provided it can be excreted. It is harmful if it is retained. It is our practice to give 1 cc of mercupurin intravenously. If there is no diuretic effect at the end of twenty-four or thirty-six hours, we give 2 cc intravenously. If this causes no effect, the diuretic is discontinued. But as long as the mercurial diuretic produces diuresis, I have no fear that it will do any real damage, and I give it in the presence of renal insufficiency, in the presence of hematuria, and in the chronic stage of the disease where it is necessary to relieve the edema for the patient's comfort. However, I do not expect it to alter in any way the course of the disease.

Sometimes it becomes necessary to remove fluid mechanically. This is rare and is always beset with danger because of the possibility of infection. It is very easy to infect edematous tissue. Southey's tubes and needles, which were used years ago, frequently caused cellulitis and in some cases erysipelas. We now resort to the mechanical removal of fluid only from the pleural spaces and from the peritoneal or pericardial cavity when it is present there in such amounts as to cause distress.

I will finish by saying that in the hypertensive stage of the disease there is no rational treatment. The hypertension cannot be in-

fluenced when it has become permanent in the stage of the contracted kidney. The anemia is almost impossible to control with iron, liver, or any kind of treatment. Transfusions have been recommended, but their effects are temporary and do not alter the course of the disease. The diet in the hypertensive stage of the disease, I think, should be unlimited, the patient should be allowed to make his own choice. If there is edema, again sodium should be restricted. If there is protein loss, the patient should be encouraged to take more protein than the normal, perhaps about 100 or 125 Gm a day, but apart from those two changes it is my experience that the diet might just as well be left to the patient to insure as much comfort as possible during the remaining days of his life.

DR DuBois. Dr Shannon will continue with the physiologic aspects.

DR JAMES A. SHANNON. At the present time it is impossible to establish a rational basis for therapy in glomerulonephritis, since knowledge of the disease process, in terms of physiologic mechanisms, is inadequate. We can, however, define the therapeutic problem. The acute process, although important in itself, derives its major significance from the fact that it initiates, in some 25 per cent of the cases, a condition that will eventuate in renal insufficiency. Function in these cases as measured by gross renal function tests may remain within normal limits for a number of years following the acute process. There is present, nevertheless, a progressive destructive lesion. The therapeutic problem is twofold: first, the devising of means to prevent the acute process from entering the progressively destructive stage, and, second, the interruption of the progress of the latter following its inception.

It is obvious that such therapy, if rational, must rest upon a knowledge of the factors that tend to enhance or oppose the fundamental processes responsible for the progress of the disease. This knowledge is not available at the present time. I do believe, however, that there is sufficient in the way of experimental evidence to permit us to speculate a little on what these factors may be.

First we must decide whether chronic diffuse glomerulonephritis is characteristically episodic in nature or whether it may be considered to be a disease that, once initiated, may progress to its final termination in the absence of the initiating agent. I believe that many or most clinicians and pathologists will accept the probability of the latter alter-

which he frequently noted a diuresis. We have not used that because we hesitate to put so much water into the circulation at a time when very little is being excreted. The restriction of sodium is the only rational mode of attack on this type of edema.

The mechanism of the hypertension is poorly understood. At one time it was thought to be due to injury of the systemic vessels resulting in spasm. In the light of Goldblatt's work, the mechanism may be impaired renal blood flow. As the mechanism is still not established, the treatment of hypertension is still without rational basis. As I have already mentioned, the encephalopathic manifestations such as convulsive seizures and coma associated with hypertension may be controlled by reduction of intracranial pressure. In some instances the blood pressure tends to fall, at least temporarily, when magnesium sulfate is given intravenously.

There are differences of opinion as to when the patient may be allowed to be up and about. It is my belief that patients should be allowed out of bed when the hypertension and the edema have disappeared. The persistence of urinary abnormalities is no indication for keeping a patient in bed. Proteinuria and hematuria may last three to six months longer, even in those patients who ultimately recover. It does not seem reasonable to keep them confined to bed for that period of time.

As to the question of the removal of suspected foci of infection, it is the general belief, and has been my experience, that the course of the disease remains uninfluenced by the removal of suspected foci of infection. There is little question about what to do when there is peritonsillar abscess or localizations of pus which are obvious and can be reached. They should be removed promptly. Their removal should not be delayed until the disease has subsided.

The general feeling is that suspected foci, such as tonsils that look as though they might be infected or on culture show large numbers of a beta hemolytic streptococcus, are often removed too soon. In 30 or 40 per cent of such patients there is a recurrence or an exacerbation of the nephritic manifestations, and tonsillectomy is followed by recurrence not only of hematuria but even of edema and hypertension. It is now believed that where suspected foci are not obviously purulent infections they should be removed four to six months or even longer after the subsidence of the systemic signs of the disease.

There is no general agreement concerning

diet in the acute stage of diffuse glomerulonephritis. The view that protein is harmful to kidneys rests on observations made on smaller animals which, I think, now would not be considered valid. There seems to be no clean-cut evidence in man that protein injures the kidneys in any stage of renal disease. Furthermore, it is beneficial in one form of renal disease or one stage of it. The recent experimental work of Smadel and Farr, in which nephrotoxic nephritis terminated in uremia when a high protein diet was used while the same disease in animals on a low protein diet went on to recovery, makes the question of proteins in the diet a little more pertinent at the moment, but again this is an observation in animals which may or may not be applicable to man.

Our practice at Bellevue is to allow the patient in an acute diffuse glomerulonephritis to take a regular ward diet and to restrict sodium. We have never made any attempt to put the patients on any kind of a dietary regimen, and our morbidity and mortality figures correspond favorably with figures obtained on patients treated with strict regimens.

I might say there is no real objection to keeping patients on a low protein, high carbohydrate diet, but there does not seem to be any sound basis for taking it too seriously. So much then for the acute state of the disease.

About 20 to 25 per cent of these patients will pass into a chronic stage which may take one of two forms: either the nephrotic form or the hypertensive and also, of course, combinations of both. The nephrotic stage of the disease is the result of persistent loss of protein in the urine with depletion of plasma protein at a time when the hematuria and the hypertension have disappeared, resulting in a diminution of plasma protein and low osmotic pressure. The result is massive edema. The rational treatment would appear to be the replacement of the protein which is lost in the urine. That, as you know, is the basis of the high protein feeding in this stage of renal disease. From my own experience the administration of a high protein diet is not often associated with any recognizable increase in plasma protein or diminution of edema. However, the diet should be high in protein on the grounds of general nutrition.

The edema calls for treatment because the patient wants it and not because it is of any real importance so far as the course of the disease is concerned. Sometimes the edema becomes so massive that patients must have

lar bed, impaired as it may be, could, given a longer time, expand to satisfy the tissue need

If this were so, we would be able to interrupt the sequence of events which results in the eventual destruction of the renal tissue as previously outlined

I do not feel that as the result of these considerations we are now in a position to advise the restriction of protein intake as the logical therapy in this disease, particularly, since there is already loss of considerable amounts of protein in the urine and since the restriction of protein intake carries many consequences that have nothing whatsoever to do with the processes going on in the kidney. We do suggest the following that the forces acting in the normal individual and in the normal kidney have the potentiality of converting an initial process into one that is then more or less self-propagating, that regulation of dietary protein may be a means by which we can control these forces, and, finally, that with the aid of the precise functional methods available at the present time these propositions can be put to test, first experimentally and then clinically. I am aware that in certain respects this formulation conflicts with the views of Dr Goldring

Dr DuBois We are particularly anxious to bring out differences in principle between the experimental work of the laboratory and the observations in wards with patients and so, Dr Goldring, perhaps you would like to come back now

Dr Goldring Not right away

Dr DuBois The meeting is open then for a general discussion. Are there questions on either of these presentations?

Dr Ephraim Shorr I wondered whether Dr Goldring could tell us if chemotherapy is indicated in the acute Bright's disease or whether he regards the process as past the infectious stage and hence past influence by such substances as sulfapyridine and sulfanilamide. One now and then hears of what seem to be striking results, and I wondered whether your experience confirms them.

Dr Goldring I have had no experience with chemotherapy in acute nephritis, but it would be my impression that the renal lesion having been initiated would not be influenced by such therapy

Dr Harry Gold If you had a patient with an acute tonsillitis or septic sore throat who developed acute diffuse glomerulonephritis, would you use sulfanilamide with the idea, first, of influencing the primary infec-

tion, and, second, of preventing the involvement of the kidney?

Dr Goldring I would not hesitate to use it in the presence of a renal lesion. I expect it probably would help the local infection, but I doubt very much if it would influence the process in the kidney that has already begun

Dr John E Detrick When the use of sulfanilamide was first introduced, several clinics tried it and I believe they thought, if anything, it made the patient worse. I understand further clinical trials were planned at the Johns Hopkins Hospital and at Rochester, but I have not heard of the outcome of their second trial. Have you?

Dr Goldring The results have not been encouraging

Dr McKeen Cattell The damage in general is supposed to be a toxic process rather than a direct infection of the kidney parenchyma, is it not?

Dr Goldring That may be the answer

Dr Gold Is there anything to be said about the pH of the urine in nephritis? In experimental nephritis, MacNider found that sodium bicarbonate exerted a beneficial effect on the course of the kidney damage. Does that apply to humans? I wonder whether the acidosis that occurs in the late stages of nephritis might not be due to the protective excretion of large quantities of base in the course of the disease, and, if so, would sodium bicarbonate or other alkali prove beneficial?

Dr Goldring When we go back to some observations by Osman, made a good many years ago, it appears that he was convinced at that time and he still believes that the alkalizing treatment is a very useful treatment in nephritis. I do not know of anyone who has repeated his observations

Dr Detrick In Baltimore in Dr Longcope's clinic, they were using the alkaline ash diet in every patient with nephritis

Is there not experimental work in animals to show that the kidneys when putting out an alkaline urine do less work? If arterial and venous oxygen saturation of the blood is measured and if the amount of oxygen used is calculated, the work done when the kidney excretes an alkaline urine is less per cubic centimeter of urine for the same concentration than would be expended on an acid urine. Is that correct?

Dr Shannon Before answering Dr Detrick's question directly, I should like to stress two physiologic facts which are too fre-

native with respect to the disease in man. Certainly the work of many in the field of experimental pathology shows this to be true in a variety of experimental nephritides—that is, having once injured the kidney by one means or another, a sequence of events is initiated which in itself will eventuate in renal failure. If this be true in man, then it is logical that we look for some series of variables within the normal economy of the body which are the propagating factors in the disease following its inception.

It is common knowledge that surgical ablation of renal tissue is followed by compensatory hypertrophy of the remainder and that this hypertrophy is accompanied by an increase in renal blood flow to serve the regenerating tissue. Furthermore, Chanutin, Addis, and others have demonstrated in the rat that an important variable determining both the rate and extent of this compensatory hypertrophy is the protein content of the diet. That protein is important in the renal economy is evidenced by other observations. Many years ago MacKay demonstrated in a series of animals including the dog that there is a close correlation between protein intake and renal weight. Also of importance in this relation are the observations of Van Slyke and his collaborators and ourselves that in the dog both renal blood flow and glomerular filtration rate is drastically affected by the protein content of the diet. When I say drastically I mean to the extent of some 300 per cent.

I would quote the observations of Smael and Farr in a slightly different manner than used by Dr Goldring. They demonstrated that following an initial renal insult, the result of an injection of a specific nephrotoxin, the addition of protein to the diet caused progression of the renal lesion to final insufficiency. This effect occurred in only one of three strains of rats, but it is to be expected that the inbreeding used in the development of a strain will naturally tend to enhance or suppress a susceptibility such as this. These observations are important in part because the disease, as described histologically, simulates in many ways glomerulonephritis but more so because the agent they used to cause this progression of the disease, protein, is one which we know controls to a considerable degree both the regeneration of renal tissue and renal blood flow. Although these conclusions are derived from experimental animals, it is unlikely that they will not obtain for the renal tissue of man.

If one can accept the view that acute diffuse glomerulonephritis is a disease characterized by renal tissue ablation by one means or another and at the same time by impairment of the lability of the renal vascular bed because of specific injury, one has the variables that at least theoretically could cause progression of the condition to ultimate renal insufficiency. The sequence of events from this point of view would be first, a glomerulitis with ablation of some renal tissue directly by the disease process or indirectly through anoxia, then, a compensatory hypertrophy associated with relative renal ischemia due to the initial impairment of the renal circulation, and later, the development of vascular hypertonus, local or general, or the enhancement of existing hypertonus along the lines of the Goldblatt principle, resulting in the destruction of more renal tissue and so on into renal failure. The crux of this hypothesis is that due to a vascular injury occurring with the renal tissue ablation the expansion in the renal blood supply cannot keep pace with the tendency of the renal tissue to undergo compensatory hypertrophy.

The therapeutic indication, if this be the case, is obviously the interruption of this vicious cycle or the prevention of its inception. I hesitate to mention the restriction of protein intake as a possible therapeutic measure, but logic demands its consideration.

Addis suggests that the renal hypertrophy that follows the ablation of tissue by the disease is a feature in the compensation to the disease process which is to be encouraged. He suggests a dietary regimen that gives protein to aid in the regeneration of renal tissue yet does not yield such substances as creatinine, uric acid, etc., which will increase the osmotic work of urine formation. I would not suggest that we have such a superabundance of renal tissue that we can lightly lose large quantities and suffer no physiologic handicap. I would suggest, however, that there is little need in the ordinary case of acute diffuse glomerulonephritis to worry about the immediate loss of renal tissue and that therapy should be guided by the more remote consequences of this loss. In our point of view the important indication is to permit a normal restoration of the balance between renal tissue, normal and regenerating, and the renal blood flow or rather to aid in the restoration of the balance, since it apparently is satisfactorily struck in some 75 per cent of the cases. It may be that if one were to slow up the regenerative process by a limitation of dietary protein the renal vascu-

case I gather you do relatively little therapeutically except keep the patient absolutely quiet and provide a diet with low sodium

DR GOLDRING Yes

DR DuBOIS Then treatment has not changed so much in the last thirty or forty years That is about what was done before when the Imperial drink, or alkaline drink, was used That has been given up

DR GOLDRING That has been given up as far as I know

DR DuBOIS But it may come back

DR GOLDRING It may come back

DR DuBOIS The clinicians have had all these years to try out various methods of treatment Nothing impressive in the way of preventive measures has as yet appeared, has it?

DR GOLDRING Not as far as I know

DR DuBOIS It looks as if we would have to wait for more experimental work, Dr Shannon, the type of work that you are doing

DR SHANNON Of course my point of view is generated largely from the fact that nothing has been developed that seems to have any influence on the course of this disease whether the therapy is based upon bacteriologic, immunologic, biochemical, or clinical considerations If this is the case, it seems to me to be fair evidence that we may have inherent in the functional makeup of the kidney the necessary variables which, once brought into play in the proper manner, can be self-propagating to a final termination Whether or not the variables I have mentioned are the ones is, of course, another story

DR DuBOIS I have one final question of Dr Goldring Are the clinicians doing things now that may be damaging to the kidney in acute nephritis?

DR GOLDRING I do not think so I think, as Dr Shannon does, that this condition, whatever it is, this diffuse vascular disease, starts and runs a set course, and I do not think it is within the doctor's power to do much harm or much good

DR DuBOIS Dr Goldring, will you summarize the ground covered in this conference?

DR GOLDRING The material presented at this conference leads to the conclusion that

nephritis in its chronic stages is a progressive disease, which is very little influenced by any regimen of treatment Further, it appears that little can be done to alter the percentage of cases of acute glomerulonephritis which become chronic The discussion of the underlying pathology indicates that we are still in the dark regarding the underlying mechanisms in the disease, but it appears probable that anatomic and physiologic factors inherent in the kidney provide a self-propagating system which eventually results in a degree of renal failure incompatible with life Thus, if the vascular supply failed to keep pace with the hypertrophic parenchymal changes, a vicious circle would be set up, resulting in a progressive decrease in functioning renal tissue

Experimental evidence was cited indicating that a high protein diet tends to cause hypertrophy of the kidney and thus with the observation of a lower survival rate in rats, following renal damage, when the diet is high in protein, suggests that a certain amount of control might be exerted by regulation of the protein intake We do not know to what extent these results can be transferred to man, and, because of other possible undesirable consequences of a low protein diet and the failure to influence mortality statistics, limitation of proteins in nephritis is not recommended Further, no advantage appears to be gained by limiting fluids The treatment of edema is not regarded as important unless it is causing the patient discomfort, and the only rational therapy is the restriction of sodium salts

Treatment then is almost entirely symptomatic Useful therapeutic procedures are for paroxysmal dyspnea, morphine, and phlebotomy, for congestive heart failure, intravenous ouabain supplemented with digitalis by mouth for convulsive seizures, magnesium sulfate, for coma in an acute attack, slow drip spinal tap, for anuria, there is no useful procedure, for uremia, infusion of hypertonic solutions, for acidosis and dyspnea, intravenous sodium bicarbonate and normal saline, for edema, sodium restriction and the mercurial diuretics

It may be again emphasized that as yet we have no therapy that has an appreciable influence on the course of the disease

THE GREAT LOVER

Gently, he pushed her quivering shoulders back against the chair She raised beseeching eyes in which faint hope and fear were struggling From

her parted lips the breath came in short, wrenching gasps Reassuringly, he smiled at her

Bzzzzz, went the dentist's drill — *Widor*

quently overlooked when questions such as these arise. In the first place, the physiologic work of the kidney is so complex that it is usually difficult to relate a change in the energy consumption of the organ as a whole to any specific experimental variable. Van Slyke and his collaborators have demonstrated in the unanesthetized dog almost direct proportionality between renal blood flow and oxygen consumption. Other than this I know of no well-established correlation relating to energy consumption, and even here it seems likely that the changes in these two variables may have been the result of a third factor. Second, in terms of the composition of the blood and urine, the energy expended in urine excretion is only a small fraction, about 2 to 4 per cent, of the energy turnover as calculated from renal oxygen consumption. Now when one speaks of an alkaline urine, one speaks relatively, since the limit of alkalinity is about equal to pH 8.0. An alkaline ash diet would produce a urine with a pH somewhere in the neighborhood of 7.0. It may be that the operations that result in an acid urine are costly in terms of energy expended, whereas the formation of a urine at pH 7.0 would require no work to be done on the hydrogen ion. It is difficult to see, however, how this specific operation can be important in terms of the energetics of the organ as a whole.

DR DETRICK: Our main idea was the same as bedrest—that is, getting the kidney to do as little work as possible.

I should like to hear more discussion on the question of rest of a patient as a means of diminishing the work of the kidney.

DR GOLD: Bearing on Dr Detrick's question is the observation that kidney function tests show a fairly marked fall of renal function after violent exercise in athletes.

DR SHANNON: I feel that here again one is defeated by the complexity of the mechanism of urine formation. Theoretically one must consider that the most restful condition for the kidney is a state of moderate diuresis, and this is probably so in practice. Actually, however, measurements of oxygen consumption during periods of diuresis and concentration show little difference in the energy turnover in the two states. This point of view is stressed by the consideration that in a day about 180 L. of water and 1 Kg. of salt are filtered, of which all but about a liter of water and a few millimols of salt are reabsorbed. Other similar operations, which must similarly be described by almost astronomic figures, find no representation in the urine at all. It

is almost certain that the vast majority of renal work goes into this type of process. It follows from this that when we attempt to relate a urinary finding to the energetics of the organ as a whole it makes up too small a part of the complete cost of urine formation for us to gain a satisfactory correlation. I feel that many therapeutic aims (such as giving the kidney rest), though they seem superficially feasible, are by the very nature of the organ impossible. I do not mean to say that these therapeutic aims and measures are in themselves incorrect, but I do say that they must find their justification from clinical or experimental trial rather than theoretic considerations.

DR DETRICK: We do not like to limit fluids in a patient with an acute diffuse glomerulonephritis and even avoid doing a concentration test. One of the best diuretics is water and if we can keep the kidney well supplied we feel we have done something. In the light of our present knowledge do you think it would be best to give the alkaline ash diet with the maximum amount of fluid that can be tolerated without producing edema? As to protein, we give them a regular diet as you do.

DR SHANNON: I do not believe that there is any theoretic objection to an alkaline ash diet, and there is certainly none to the administration of adequate amounts of water. With respect to the alkaline ash diet, however, it is a question in my mind whether or not one can justify it on any other basis than the fact that it seems to do the patient some good. However, if this is true, it is justification enough.

DR DUBOIS: I think your statement, Dr Shannon, that the kidney does least work in moderate diuresis is one that would be new to most clinicians. It seems to me that that is an important point of view that has been brought out by the newer physiology. Is the difference significant clinically?

DR SHANNON: I do not believe so. I feel that the amount of energy that goes into the formation of a concentrated urine as compared to the energy consumption of the organ as a whole is too small. On the other hand, there may well be other advantages to be gained in presenting a dilute rather than a concentrated urine to the cells of the distal portions of the tubules.

DR DUBOIS: It seemed to me that Dr Goldring in his suggestion of treatment concentrated on the complications that came up when certain aspects of acute nephritis became very prominent but that in the ordinary

FIG 1

FIG 2

doors could recognize objects only at about the same distance. Within two weeks the vision gradually improved, the scotomas disappeared, and the patient regained his previous visual acuity inside of a month. The peripheral fields remained practically unchanged. The following methods of treatment were directed against the tryparsamide amblyopia: intravenous injections of sodium thiosulfate, 50 per cent sucrose solution by vein, potassium iodide by mouth, and spinal puncture. He was seen at home four days after the eighty-second dose of tryparsamide. An eye examination (by D F G) was made on May 8, 1938. The optic disks remained a faint yellow-white, had sharp outlines and were but little excavated, in fact they had remained unchanged from the previous examination. The subjective symptoms revealed a visual acuity reduced to H/M at 18 inches and a large central scotoma for form and colors (taken on an improvised screen). The diagnosis was retrobulbar neuritis.

An eye examination (by D F G) on July 14, 1938, showed whole of disk yellow-white with sharp outline, fine changes in each macula, right more than left. The optic atrophy appeared about the same. Vision was 20/30 in right eye and 20/40+ in left eye. They were corrected to 20/20 in right eye and 20/30 in left eye. There was a good recovery from attack of retrobulbar neuritis. The fields are shown in Fig 3.

Primary syphilitic optic atrophy is a progressive lesion often ending in blindness. It is one of the few manifestations of syphilis that is

FIG 3

infrequently checked by antisyphilitic therapy. Much difference of opinion exists as to the proper place of arsenicals in treatment. Some feel that they further endanger vision, while others believe that they offer some hope of arresting the lesion.

Tryparsamide is a white, odorless, crystalline substance, readily soluble in water and containing 25 per cent of arsenic. It is related to atoxyl and arsacetin. The drug is rapidly eliminated, 88 to 95 per cent in twenty-five hours (Stokes¹), and it is remarkably noncumulative. It is a pentavalent arsenical in contrast to trivalent arsphenamine and neoarsphenamine. Stokes¹ quotes Young and Loevenhart to the

Case Report

DRUG ALLERGY WITH SPECIAL REFERENCE TO TRYPARSAMIDE

JOSEPH R. WISEMAN, M D, and DAVID F. GILLETTE, M D, Syracuse, New York

VISUAL disturbances accompanying the administration of tryparsamide have been reported by many observers in various parts of the world, but the case about to be described presents certain unusual features

Case Report

Mr A. G. D., aged 47, a widower, was first seen November 5, 1932. He had retired because of ill health from the restaurant business one and one-half years before this date. In March, 1932, he had a "stroke" that paralyzed the right side of the face, right arm, and right leg, although consciousness was retained. He partially recovered and was able to walk by dragging the right foot. On November 4, 1932, he developed weakness of the right half of the body and became unable to get out of bed. There was retention of urine and incontinence of feces. The patient had always been well but admitted a primary chancre at the age of 18. The family history was unimportant.

Physical examination showed a rather small man of fair development and nutrition. His mind functioned slowly, and he responded to questions deliberately but accurately. The left pupil was greatly dilated, neither pupil reacted to light and only slightly to accommodation. His blood pressure was 130/90. The lungs and heart were negative. The urinary bladder reached half way to the umbilicus. The right arm and leg presented spastic paralysis, and the left arm and leg revealed marked muscular weakness. Both knee jerks were exaggerated, especially the right. Right ankle clonus and left Gordon were obtained. Bilateral Babinski reflexes were present. He was unable to turn in bed or help himself. The blood Wassermann was 3 plus, both antigens, spinal Wassermann 4 plus, both antigens, very faintly hazy, globulin faintly positive. The cell count was 32. The urine was clear specific gravity, 1.015, albumin, 0, sugar, 0, rare leucocyte.

He was placed upon alternating courses of iodobismutol and sulfarsphenamine intramuscularly. After several months of treatment remarkable improvement was evident. He regained good use of the left arm and leg, with considerable motion in the spastic right arm and leg so that he could walk to the toilet with assistance. Control of the bladder and rectal sphincters had become normal, and the mental retardation had entirely cleared. By March, 1934, after sixteen months of nearly continuous treatment, he was able to go downstairs and walk on the street with the aid of a cane. The right foot turned inward and the right hand was partially flexed.

An eye examination (by D. F. G.) on March 11, 1933, revealed external eyes normal, vision—

right eye, 20/15 and left eye, 20/15, muscles normal. The right pupil reacted slightly to intense light, the left pupil, three times as large, had no reaction to light, both reacted to accommodation (attempted) and convergence—early Argyll Robertson pupils. Media were clear. Fundi had slight yellow tinge, and disks, nasal half was yellow-white, with an old perivascularitis (pigment along sheaths of some vessels). He had paresis of accommodation. Confrontation fields were beginning to contract, color perception was normal. The diagnosis was early optic atrophy (Fig. 1). On March 27, 1933, he was given glasses for reading +2.75 *oculus uterque*.

A course of ten weekly intravenous injections of tryparsamide was started April 29, 1934, beginning with a dose of 1 Gm and soon increasing to 2 Gm.

An eye examination (by D. F. G.) on June 25, 1934, showed vision—right eye, 20/15 and left eye, 20/15, pupils unchanged, fields charted, primary optic atrophy. On September 11, 1934, vision in the right eye was 20/30 and in the left was 20/25, the fields were charted. On January 2, 1935, vision in the right eye was 20/30 and in the left was 20/25, the fields were charted. There were no other changes.

Meanwhile he had received alternate courses of iodobismutol (2 Gm) and tryparsamide (2 Gm) with rest periods between. By October 20, 1936, two and one-half years later, he had been given a total of eighty tryparsamide injections, seventy of which were 3-Gm. doses. After tryparsamide was stopped he took courses of sulfarsphenamine, iodobismutol, or bismuth subsalicylate twice a year with longer rest intervals between.

An eye examination (by D. F. G.) on April 19, 1938, revealed vision—right eye, 20/30 and left eye, 20/25. The fields are shown in Fig. 2.

Soon after this eye examination, two years after the last dose of tryparsamide, the decision was made to administer further treatment with this drug in an effort to halt the optic atrophy which had slowly progressed. Inasmuch as ophthalmic reactions from tryparsamide almost invariably occur within the first ten injections and because the patient had already tolerated eighty doses with perfect ease, no apprehension was felt.

On April 24, 1938, he was given an intravenous injection of 15 Gm of tryparsamide. No untoward effects were noted, and ten days later, on May 4, 3 Gm was given. The next day he noted dimness of vision as if he were looking through a frosted window pane. Impairment rapidly increased. Things looked cloudy as if in a snow bank, and he had difficulty in seeing trees across the street. He was able to distinguish fingers at 3 feet with some effort. A few days later the patient became unable to recognize faces at 10 feet and when looking out-

comes greatly reduced, but, if unrefined and un-concentrated serum is given in large amounts, serum sickness may be induced in over 90 per cent of individuals. In the field of contact sensitivity the experiments of Bloch quoted by Landsteiner¹ are of interest. Under natural conditions only a few persons become sensitive to *Primula*, but by treatment with concentrated extracts almost anybody can be sensitized—an acquired allergic state.

In the case of drug allergies, some persons show evidence of sensitivity after one or two doses, whereas others may require numerous contacts before sensitization occurs. Reactions to tryparsamide usually occur within the first ten injections. Moore² goes so far as to state that "if more than twelve injections are tolerated without reaction, its subsequent appearance need not be feared." Nevertheless, in our reported case, eighty injections were well tolerated, an interval of two years elapsed, two injections were given, and a severe visual reaction occurred.

Fitz-Hugh³ considers agranulocytic angina to be due to an acquired sensitivity of the leukocytes to certain drugs and other allergens. He makes use of the theory of "conditioned deficiency," described by Castle in pernicious anemia where there is a specific gastric defect, the lack of this specific substance prevents the individual from utilizing even a superior diet to form normal blood elements. Fitz-Hugh applies this idea to drug allergy and alters it by supposing influences that divert and modify normal action into an effect of conditioned toxicity which changes the usual effect of the drug into an allergic response. Among states that may condition hematologic sensitization are mentioned disorders of the liver and spleen, vitamin deficiency, genetic factors (atopy), endocrine influences, intestinal putrefaction, states of fatigue and shock, and prior hemopoietic disease. Rhoads and Miller^{4,5} showed that dogs conditioned by a deficient diet (called the black-tongue diet) became anemic when they were given aminopyrine or crystalline indole. Neither the deficient diet alone, aminopyrine, nor indole would produce the same result.

Leinfelder¹⁰ reports the case of a man, aged 52, who was given a single intravenous injection of 1 Gm of tryparsamide. Three days later he became blind. He died of uremia nine days after tryparsamide was administered. Autopsy showed acute degeneration of the ganglion cells of the retina and of cells in the inner nuclear layer. No evidence of acute degeneration was found in the optic nerves and tract. The central nervous system and the remainder of the organs showed no related changes. A striking fact in reports of pathologic changes in tryparsamide reactions is the absence of tissue changes outside the eye and optic pathways. Leinfelder felt that his case suggested idiosyncrasy to the drug. It is our thought that it can be regarded as drug

allergy, either due to sensitization from the previous administration of arsenic or possibly to hereditary allergy.

The frequency of visual reactions to tryparsamide is by no means great enough to warrant the assumption that the drug in itself is toxic for humans. Sloan and Woods¹¹ reported that of 241 patients treated with the drug 10.2 per cent showed subjective visual reactions and 5.5 per cent showed objective evidence of damage. They quote Lilie to the effect that of 2,087 patients treated with tryparsamide, 5.33 per cent had subjective eye reactions and 3.53 per cent had objective eye reactions. In 1929, Phelps,¹² of the United States Navy, reported 4,488 doses of tryparsamide given in the Navy with no visual reactions.

If the drug is withdrawn at the first evidence of trouble, recovery is the rule, but, if its use is persisted in, more serious results may follow. In rare instances the occurrence of dermatitis has been reported.

Allergic reactions to drugs and chemicals appear to fall into two groups: (1) general reactions—which are frequently seen and include fever, polymorphous skin rashes, joint pains, edema, and leukopenia, and (2) local reactions—less often encountered in a localized tissue or special shock organ. An example of a typical action of an allergen on a shock organ is seen in pollinosis where the respiratory tract is almost exclusively involved—the upper part in hay fever and the lower portion in asthma. In the case of drug allergy due to aminopyrine, the hemopoietic system seems to be the shock organ and agranulocytosis results. With cinchophen sensitivity, the liver usually bears the brunt of the burden. Tryparsamide reactions affect the visual tract almost exclusively. As new chemical compounds are discovered and used, additional allergic responses are sure to occur.

Summary

A case of syphilitic meningoencephalitis is reported. Within two years the patient received a total of eighty injections of tryparsamide (approximately 220 Gm.) with no unfavorable symptoms whatever. After an interval of two years, tryparsamide treatment was again resumed. Following the second injection a tryparsamide amblyopia occurred, followed by eventual recovery.

The symptoms of drug allergy are usually general in nature and somewhat similar for most drugs. They consist principally of fever, polymorphous skin eruptions, arthritic and muscular pains, etc.

A smaller group of drugs appears to produce allergic symptoms chiefly in a localized tissue or a single organ. Tryparsamide appears to fall in this class.

effect that the biochemical reason for the production of optic nerve lesions by tryparsamide is the general rule that the presence of the amino groups in the para position to the arsenic, regardless of its valence, induces tropism for the optic nerve. In man, optic nerve injury is markedly more frequent in the presence of previous injury to the optic tract by syphilis—the third neurone of the optic tract is involved.

Allergy to drugs has been described by Tuft* as a condition of hypersensitiveness in which an amount of a medicinal agent, nontoxic for an average individual, is followed by an unusual but characteristic reaction. It is distinguished from the toxic action of the drug because the latter produces symptoms that are in exaggeration of the normal physiologic action. Large doses of salicylates produce ringing in the ears of most individuals. In our intern days the treatment of rheumatic fever included the administration of large doses of salicylates until "the birds began to sing." On the other hand, a single 5-grain tablet of acetyl salicylic acid may cause death in an allergic individual. The symptoms produced by the toxic or physiologic action of a drug differ widely according to its chemical constitution. The symptoms of drug allergy, however, regardless of the drug given, are more or less the same with certain exceptions. They consist chiefly of fever, multiform skin eruptions, edema, arthritic or muscular pains, adenitis, and leukopenia. The duration is usually short and the course self-limited. It is interesting to note that the symptoms of serum sickness induced by the therapeutic injection of animal serums are similar to the manifestations of drug allergy.*

Tuft* further states that, as a rule, sensitivity exists to only one element or chemical group in a given drug. Sensitivity to quinine usually involves only the levorotary groups, whereas the dextrorotary relatives, such as quinidine, may be well tolerated. In patients who have become sensitized to pentavalent tryparsamide, the trivalent arsenicals (arsphenamine or nearsphenamine) may possibly be well borne.

The chemical substances that produce drug allergy are of low molecular weight and probably under ordinary circumstances possess no antigenic activity. This is in contradistinction to inducible proteins of large molecular size which induce the formation of antibodies and cause anaphylaxis. Landsteiner² believes that a drug or chemical molecule may attach itself to a protein molecule within the body, thereby forming a new protein that may stimulate the formation of specific antibodies. On subsequent contact an allergic drug reaction may result. Landsteiner is of the opinion that the existence of some kind of antibodies fixed in or on the cells is not disproved by our failure to find them with present methods.

The reaction to tryparsamide described in this communication does not fall in the group of exaggerated physiologic, i.e., toxic, reactions nor does it belong among the known symptoms of drug allergy in general. The episode was not accompanied by severe headache, rise in blood pressure, erythematous blush, or convulsions as has been reported in similar reactions. There was no typical optic neuritis, but there was a transitory retrobulbar neuritis that left the patient with his former visual acuity, fields, good color sense, light adaptation, and improved accommodation. The matter of tropism for, or specificity of, action on a tissue or organ of the body comes into consideration.

The paper of Sugg⁴ presents some pertinent observations. In susceptible persons cinchophen seems to have a selective affinity for the liver, producing a toxic cirrhosis which may be associated with acute yellow atrophy and a fatal ending. Many doses of cinchophen over a long period of time may appear to be well tolerated when unexpectedly toxic symptoms appear. The drug may be well taken for an indefinite time, be discontinued, and then be followed by alarming symptoms when again administered, even after a lapse of months or years. This resembles our experience with our patient, A. G. D. Sugg reminds us of the observation that a drug may be well tolerated for a long time when for an unknown reason the individual becomes sensitized to it and toxic symptoms occur—the refractory or delayed period of sensitization which may last days, weeks, or years. Some of his reported patients took cinchophen in a wide range of doses without symptoms, and later when a smaller dose was taken, they became toxic. Sugg suggests three possibilities: (1) The liver damage may follow an abnormal susceptibility because of certain local predisposing conditions, (2) silent liver damage may have been caused by earlier doses, and accentuation of the damage occurs upon readministration after months or years, (3) the toxic manifestations may be allergic in nature.

Drug allergy may be of two types—hereditary or acquired. In the hereditary or pathologic form, a person who has never before taken a particular drug has an immediate allergic reaction, often of severe degree, on its first administration. It is assumed that sensitivity to a chemical radical in the drug has been transmitted through the germ plasma or possibly has been acquired in utero through the mother's blood. The patient knows of no previous contact with the drug in question. In the more common acquired or physiologic type of drug allergy, symptoms usually occur after several or many doses of the drug. There is always a period of incubation which may be days, months, or years in duration. Serum sickness, which closely resembles drug allergy in its symptoms, is also an acquired allergy. If concentrated refined serum is given in small amounts, the number of serum reactions be-

Medical News

County News

Albany County

Governor Lehman spoke on "Your Health as a National Asset During Mobilization" on December 12 at Albany Law School in the first of a series of community meetings sponsored by Albany Medical College, Albany Hospital, Albany County Medical Society, and the Hospital Council of Albany.

The meetings, which will take up all phases of community health during defense mobilization, will have recognized experts as leaders. Each will stress a phase of health maintenance.

Subsequent addresses will outline the place of the family doctor in community health maintenance, how to achieve best possible nutrition, prevention of epidemics, control of dangerous insect pests, and how to protect a community from effects of anxiety, uncertainty, and fatigue.

The annual meeting and election of officers of the county society were held on December 11. The annual dinner was given on December 18 in the DeWitt Clinton Hotel Crystal Room. The speaker was Lillian T. Mowrer, wife of Edgar Ansel Mowrer and author of *Journalist's Wife*.

Bronx County

A six-point plan for economic help to physicians absent on military duty was adopted by the county society at a recent executive session.

The plan includes the safeguarding of appointments and seniority rights of staff members absent on military duty at the following Bronx hospitals: Montefiore, St. Francis, St. Joseph's, Fordham, Bronx, Morrisania, Lebanon, and Lincoln, and the formulation of a model contract between the doctor in active service and his substitute, including a half-and-half distribution of all funds collected between both doctors, under the supervision of a special committee of the society.

The plan also provides that the society remit, in whole or in part, the dues of any member called into active service.

The officers of the county society for 1941 are as follows: president, Dr. Joseph Golomb; president-elect, Dr. Abner Stern; vice-president, Dr. Morris Cohen; secretary, Dr. Henry Friedland; treasurer, Dr. J. Adlai Keller; counsel, Dr. Maxwell Boosbaum; and executive officer, Dr. Edward C. Podvin. On the board of censors are Drs. Goodlatte B. Gilmore, Samuel Weiskopf, Frank La. Gattuta, Samuel Epstein, Vincent S. Hayward, and Abraham J. Fleischer. Elected to the board of trustees are Drs. Milton J. Goodfriend, chairman, Joshua Leiner, secretary, Harry Aranow, Philip Eichler, and Clarence H. Smith.

Broome County

The annual dinner meeting and election of officers of the county society were held at the Binghamton Club on December 10. The scientific program was as follows: *speakers*—Dr. Victor W. Bergstrom and Dr. Ulysses S. Kann and *subject*—Boeck's Sarcoid—Report of a Case

Involving Skins and Bones," shown with lantern slides.

Chemung County

Negotiations between the county society and Elmira city and relief officials on care of relief patients will be continued, the society decided on November 27 at the Arnot-Ogden Hospital.

The society also re-elected president, Dr. George R. Murphy, vice-president, Dr. John H. Burke, Sr., secretary, Dr. F. S. Hassett, and treasurer, Dr. Sven L. Larson.

The officers constitute the committee negotiating with city and county officials on the relief patient problem.

One important question is whether physicians should be paid by the city and county for care of relief patients in the hospitals. Under the present system they do not charge for such service.

The physicians also believe that the mechanics of treating indigents outside the hospitals, and receiving payment, should be simplified. Another question is whether duties of the city physician should be curtailed or continued on the present basis. Some physicians believe that relief patients seeking free treatment at the City Hall clinic should be permitted to select their own doctors instead of going automatically to the city clinic.

Society officers will have another conference with city and county officials and report at a later society meeting.

Vitamin deficiency diseases were discussed by Dr. Thomas T. Mackie of the Post-Graduate Medical School of New York City at a joint dinner of the Chemung County Medical and Dental Societies at the Mark Twain Hotel in Elmira on December 6.

Delaware County

Homer Folks Hospital was host to the county society for its annual meeting, in the form of a dinner in the hospital auditorium on December 11. Dr. Rene J. Dubos, of Rockefeller Institute for Medical Research, spoke on "The Vulnerable Structures of the Bacterial Cell."

Erie County

The county society held its annual meeting and election of officers at the Hotel Statler on December 16.

Dr. Critchlow, director of the Western New York Medical Plan, states that it has now over 1,000 members and that the outlook is very favorable. Some 750 doctors are enrolled.

Dr. Richard Cattell, of Boston, addressed the Buffalo Academy of Medicine on December 4 on "Common Duct Surgery."

Genesee County

Dr. Charles M. Graney, of Batavia, was elected president of the county society to succeed Dr. E. G. Rubby, of Byron, when 25 members gathered for the annual meeting at the Batavia Club on December 5. Dr. Raymond L. Warn, of

Physicians for the Navy

Physicians are needed in the Regular Navy and the Naval Reserve

REGULAR NAVY Applicants must be under thirty-two years of age and must have completed one year's internship They are commissioned as lieutenant (junior grade) and paid \$2,699 per year if having no dependents, or \$3,158 per year if having dependents

A limited number of **FOURTH YEAR MEDICAL STUDENTS** are admitted on acting appointments, with the same pay, given one year's internship in the Navy after graduation and then commissioned

The next examination for both these classes will be held on January 6, 1941 Applications must be submitted early in December

VOLUNTEER NAVAL RESERVE Members are not subject to the Selective Service Draft but obligate themselves to serve in time of war or national emergency If they request it, they may be given active duty at other times

There are two classes of the Volunteer Reserve

(A) *Volunteer General Service Class* Applicants must be under thirty-five years of age They are commissioned as lieutenant (junior grade) (equal to 1st Lieutenant in the Army) or, if of sufficient age and experience, as lieutenant (equal to Captain in the Army) Many will be given aviation training at government expense if they request it **INTERNS** and **RESIDENTS** are eligible to enroll in this class of the Reserve

The Surgeon General places all interns and residents on the deferred list, and they will not be called to active duty before finishing their internship or residency except in extreme urgency

(B) *Volunteer Special Service Class* This class is composed of doctors who have had special training and are under fifty years of age A limited number of general practitioners are also commissioned in this class The rank is lieutenant (junior grade), lieutenant, or lieutenant commander, dependent upon age, professional standing, and academic seniority If mobilized, they would be assigned to special service within the United States or its possessions or on hospital ships

For further information apply by letter, telephone, or call in person at the District Medical Office, Headquarters Third Naval District, Federal Office Building, 90 Church Street, New York City

pital, (c) Clinical methods by Dr Franklin M Hanger, associate physician, Presbyterian Hospital.

Dr John Augustus Hartwell, noted surgeon, formerly director of The New York Academy of Medicine and its president for two terms, died suddenly on November 30 of a heart attack on the grounds of the South Side Sportsmen's Club. He was 73.

Dr Henry E Sigerist, of Johns Hopkins, will speak on "Paracelsus in the Light of Four Hundred Years" on January 23 at The New York Academy of Medicine in the course of "Lectures to the Laity on the Art and Romance of Medicine."

Onondaga County

The following officers were elected at the annual meeting of the county society on December 3: president, Dr Leo E Gibson, vice-president, Dr Ambrose T Lawless, secretary, Dr Dwight V Needham, treasurer, Dr A Carl Hofmann, censors—Drs Ellery G Allen and Arthur N Curtiss, delegate—Dr William W Street, alternate—Dr Frederick S Wetherell.

At a dinner meeting that followed there was group singing and entertainment, including pictures of the Syracuse-Colgate game.

In his annual secretary's report, Dr Needham brought out that 465 physicians now reside or practice in Onondaga County and that the society's membership has increased from 394 to 404 in the last year.

Seven doctors he listed as engaged in active military service are Drs L J Chronis, F O Harbach, J R Kallet, W J Liccione, C D Reid, F L Ritter, and J D Thomson.

Oswego County

Dr Harwood Hollis, of Lacona, has been appointed superintendent of the Oswego County Tuberculosis Sanatorium at Orwell and will succeed his father, Dr Leroy F Hollis, 67, who recently resigned after serving for twenty-two years.

Queens County

The Physicians Art Club of the county society held an exhibition at the society building at Forest Hills from November 26 to December 10.

The Friday Afternoon Talks in December were as follows: December 6—"Common Disorders in Genito-Urinary Practice," by Dr Frank Coleman Hamm, urologist, St Mary's and Bushwick, associate urologist, Brooklyn Hospital, December 20—"Disorders of the Feet," by Dr Herbert C Fett, orthopedic surgeon, Long Island College Hospital.

Rockland County

Dr Matthew J Sullivan, of Haverstraw, for many years village and township health officer was elected president of the county society on December 4, succeeding Dr Russell L Blaisdell, superintendent of the Rockland State Hospital.

Dr E Armand Scala, of Suffern, was named vice-president, filling the vacancy created by the upward step of Dr Sullivan. Dr Dean Miltmore, of Nyack, was renamed treasurer, and Dr William J Ryan, superintendent of Summit Park Hospital, was re-elected secretary.

Dr Walter S McClellan, director of the New York State Spa Commission at Saratoga, was the principal speaker. He gave a brief illustrated talk on the value of spa therapy. Brief addresses were also made by the retiring and incoming presidents.

Saratoga County

The county society is sponsoring a postgraduate course of lectures on common diseases at the Saratoga Hospital, from November 27 to January 29.

Schenectady County

The county society held its annual meeting and election of officers at the Mohawk Golf Club on December 12.

Dr Henry A Kurth, of Schenectady, who died on December 7 at the age of 77, had practiced 50 years. One of the oldest practitioners in Schenectady, Dr Kurth was one of the three area physicians honored when the county society feted its "50-year men" at the semi-annual meeting in June. Illness, however, prevented Dr Kurth from attending the dinner.

Steuben County

Dr Richard O'Brien, of Corning, presided at the annual meeting of the county society on November 28 at Bath. The meeting followed a luncheon attended by more than 40 members.

Included in the scientific program was a paper by Dr John Alsever, of Syracuse, on "Organization of a Plasma and Blood Transfusion Service at the Medical Center of Syracuse University." A paper was also given by Dr C M Brust, of Syracuse, on "Diagnosis of Rectal Diseases."

At the election following the luncheon Dr W J MacFarland, of Corning, was named president, Dr Joseph B Mathewson, of Bath, vice-president, Dr Rudolph Shafer, of Corning, secretary-treasurer, Dr L M Kysor, of Hornell, and Dr Herbert B Smith, of Corning, delegates to the annual meeting of the State Society.

Tioga County

The annual meeting of the county society was held at the Green Lantern Inn in Owego on December 3, and these officers were elected: president, Dr C T V Redding, vice-president, Dr J B Schamel, secretary-treasurer, Dr I N Peterson, delegate, Dr W A Moulton, alternate, Dr A C Hartnagle, and censors, Drs F H Spencer, F A Carpenter, and W B Gregory.

Mr Robert Bassett of the Selective Service Draft Board spoke briefly on problems of that body. Dr Betowski, examining physician for the board, spoke on his problems and asked for cooperation.

Dr Raymond Douglas, of Biggs Memorial Hospital Staff, addressed the society on "Tuberculosis and the General Practitioner," and his talk was discussed by the members.—*Reported by Ivan N Peterson, M D, Secretary*

Ulster County

Dr William J Cranston, for many years a practitioner in Kingston and who has just retired after an active practice of 46 years, was given a notable tribute on November 19 when a testimonial dinner was given for him at the Governor

Oakfield, was chosen vice-president, and Dr Peter J DiNatale, of Batavia, will continue as secretary and treasurer. Dr DiNatale was appointed delegate to the meeting of the State Society.

A Rochesterian, Dr F W Geib, was the guest speaker.

Herkimer County

The county society held its annual meeting, banquet, and election of officers at the Mohawk Valley Country Club on December 10. Dr G J Frank delivered the presidential address.

The county society has asked the board of supervisors for power to recommend the appointment of the county consultant in the care of relief cases needing medical attention.

The present county consultant is Dr E E Kelley, Middleville. He and his predecessors have been recommended in past years by the county welfare committee of the supervisors. Appointments are made by the supervisors. The consultant receives a yearly salary of \$1,400.

The county society now asks that it be entitled to recommend the doctor for the county office, instead of the welfare committee. The society would submit to the supervisors the names of three doctors from which the supervisors would appoint one.

The office of the county medical consultant carries with it broad discretionary powers. A physician attending a patient on relief cannot undertake any care or prescribe medical attention or an operation without first conferring with the county consultant regarding the relief case.

The county society declared "The appointment of the consultant by the county has heretofore been made without recommendations by the county medical society, and, therefore, precludes any check that the profession should have upon the decision of the consultant, and lays our county wide open as to a suit for damages," as a result of the decision by one physician without the endorsement of a legitimate and recognized agency of the medical profession.

"We believe that we can give to and receive from the county of Herkimer much more co-operation resulting in much better mutual satisfaction, if the county medical society be given the sponsoring power of such appointment, and thereby be as much responsible for the diligence, efficiency and fairness of the appointee as our county," the resolution of the doctors stated.

The communication was read to the supervisors, and referred to the committee on public welfare for consideration.

Jefferson County

The county society met on December 12 at the Black River Valley Club and listened to a paper on "The Clinical Uses of Oxygen," by Dr Howard N Cooper.

Kings County

Dr William Levine was unanimously elected president of the East New York Medical Society, on December 2. Installation will take place January 7.

Other officers elected were Dr Morris Ant and Dr George Dorff, vice-presidents, Dr Mortimer Kopp, corresponding secretary, Dr

Harry E Beller, recording secretary, and Dr Max Dannenberg, treasurer.

Monroe County

Industry's defense problems and the failure of health insurance plans in other cities are given as principal reasons why the county society is delaying action on a nonprofit medical expense indemnity insurance plan.

Dr Albert D Kaiser, society president, said, as quoted in the Rochester *Times-Union*, that the physicians here had not abandoned the idea of health insurance and still hope to develop a satisfactory plan, but he did not expect any action before 1941. Plans are still being studied.

Experience with health insurance programs in other communities has not been too satisfactory, Dr Kaiser said. Several have been abandoned.

Industry, burdened with problems arising from defense needs, also is loath to undertake anything in the nature of an experiment at this time, Dr Kaiser added.

The county society began studying health insurance two years ago. In May, 1940, a laymen's advisory committee, headed by Marion B Folsom, submitted a tentative plan which has since been under consideration.

The public safety committee of the county society plans an intensive educational campaign in first-aid methods and procedure in Rochester's drive against the mounting toll of traffic crashes and injuries. The county society is also participating in the educational program to prepare for air raids and gas attacks.

Montgomery County

A series of lectures on general medicine has been provided for county society members by the State Society, starting December 3 and concluding on January 14. The topic on January 7 will be "Rheumatic Fever," presented by Dr Homer F Swift, and on January 14 the topic will be "Nephritis," by Dr John D Lytle.

Nassau County

A postgraduate course in pediatrics is being given at Long Beach Hospital, made possible through the cooperation of the county society. Similar courses are given at Nassau Hospital in Mineola, Meadowbrook Hospital, and the South Nassau Communities Hospital. Physicians from Nassau County meet once a month to hear prominent pediatricians discuss the most recent advances in medical problems.

New York County

Dr Malcolm Goodridge, professor of clinical medicine at Cornell University, was re-elected president of The New York Academy of Medicine for a two-year term on December 5.

Dr Henry Cave, assistant professor of surgery at Columbia University, was elected vice-president.

Dr George Baehr and Dr Arthur F Chace were named as trustees for five years.

This scientific program was presented "Newer Knowledge of Liver Disease" (a) Surgical aspects by Dr I S Ravdin, the George Lieb Harrison Professor of Surgery, University of Pennsylvania School of Medicine, (b) Evaluation of laboratory methods by Dr Alexander B Gutman, assistant physician, Presbyterian Hos-

Hospital News

Confidential Character of Hospital Records Confirmed

THE Court of Appeals, in a 5-to-2 decision handed down in Albany on November 26, reversed an Appellate Division ruling and held that the Commissioner of Hospitals was not required to produce confidential medical records before the City Council committee investigating charges of maladministration at Lincoln Hospital, Concordia Avenue and 141st Street, the Bronx.

When the investigation began last spring the committee, headed by Councilman Louis Cohen, Bronx Democrat, demanded certain hospital records that were deemed confidential by Dr. S. S. Goldwater, former hospital commissioner, and by Dr. Rudolph Rapp, superintendent of Lincoln Hospital. Dr. Goldwater and Dr. Rapp refused to produce the records. The committee asserted its right to see them, and when the case was litigated Justice Julius Miller, of the Supreme Court, ruled on May 3 that the committee was right. His decision was upheld by the Appellate Division on June 30. An appeal was then taken to the Court of Appeals.

The majority opinion of the court was written by Chief Justice Irving Lehman and concurred in by Associate Judges John T. Loughran, Harlan W. Rippey, Charles B. Sear, and Edmund H. Lewis. The dissenting opinion, written by Associate Judge Edward R. Finch, was concurred in by Judge Albert Conway.

Inquiry to Continue

Councilman Cohen said that the decision would not halt the investigation. Many important records, he said, are still available to the committee.

Judge Lehman held that the statutory prohibition against the disclosure of medical information applied in the case of the Council investigation.

"The policy of the legislative prohibition against the disclosure of information obtained under the seal of professional confidence," Judge Lehman wrote, "as provided in Sections 351 to 354 of Article 33 (civil practice act) would not be carried out if the court read into those sections a limitation which would render them inapplicable in any proceedings brought pursuant to the provisions of the same article to compel such disclosure."

"The statute does not provide such a limitation in express terms, and there is no ground for reading such a limitation into the statute by implication. That would not be a 'broad and liberal construction of the statute' but a distortion of its language and purpose."

Finch Dissents

In his dissenting opinion Judge Finch held that "it does not seem to me that we are compelled by statutory mandate to deny to a legislative committee whose avowed purpose is to uncover abuses, the right to ascertain the facts."

Judge Finch said he was "unwilling to assent to the proposition that the State Legislature or

its delegated authority, the City Council, are so circumscribed that the alleged maladministration may continue unchecked by virtue of a 'liberal construction' of Section 352 of the Civil Practice act."

On Oct. 1 Dr. Willard Cole Rappleye, Dean of the College of Physicians and Surgeons of Columbia University, was appointed Commissioner of Hospitals, succeeding Dr. Goldwater, who resigned to give full time to his duties as president of the Associated Hospital Service of New York. Mr. Cohen said the replacement of Dr. Goldwater by Dr. Rappleye would not affect the investigation.

Duty of the Hospital in Care of the Indigent

THE medical staff of a hospital that receives payment from public funds for the care of the indigent sick has two important responsibilities, according to a statement recently prepared by the medical board of the Albany Hospital, Albany, New York, as reported in *The Modern Hospital*.

"First, and more important," says the report, "the staff must supply medical and surgical skill of a high caliber to the public and to the medically indigent groups, and, second, it must supply such services as economically as is consistent with adequate care of the sick."

In nearly all cases, the medical staff must decide whether a patient needs to be admitted to inpatient accommodations or can be treated in the outpatient department. This has an important effect upon costs. The use of drugs and x-ray and laboratory services also affects the cost. The policy adopted at Albany seems to be a good one.

The administration also has important responsibilities. Either the admitting or the social service department must attempt to discover possible sources of income and to determine whether these may properly be drawn upon to pay for needed medical service.

When welfare departments are called upon to pay for the hospital and clinic service of indigent patients, complaints are likely to arise on each side. The hospitals may complain that welfare departments are slow in making payments, do not always accept cases that seem to be clearly their responsibility, or require too much red tape. Also, they frequently set rates that are excessively low.

Welfare directors, on the other hand, state that hospitals often consider any case as a public responsibility if there is the slightest difficulty in obtaining payment in advance, thus converting the welfare departments into "collection agencies" for the hospitals. Some hospitals abuse the privilege of admitting emergency patients without prior authorization and label an excessive proportion of their patients as "emergencies." Difficulties also arise sometimes between hospitals and welfare agencies over special charges.

Usually, the best solution to these problems is

Clinton Hotel by members of the staff of the Benedictine Hospital

Wayne County

Dr James L Davis, Newark, was elected president of the county society at the annual meeting at the Hotel Wayne in Lyons on December 3

Other officers elected are as follows Dr George Pasco, first vice-president, Dr Frank Wood, second vice-president, Dr Thomas C Hobbie, secretary and treasurer, Dr Allen, Dr Besemer, and Dr M Carmer, censors, Dr Ralph Sheldon, delegate, and Dr S Houston, alternate

Dr Lloyd Griffith Lewis, associate professor of

urology in The Johns Hopkins Medical School, Baltimore, presented a paper on "Danger Signals in Urology" Dr William Eikner, of Clifton Springs Sanitarium, and Dr Albert Crance, of Geneva, also were present and discussed the paper The society plans to run a postgraduate lecture series during the coming year

Westchester County

The White Plains Medical Society held a regular meeting at the Gedney Country Club on November 12 Mr H D Margolies, author of the book, "Guide to Workmen's Compensation," spoke on the "Medical and Legal Aspects of Workmen's Compensation Practice" About 40 members attended

IT'S A SOLDIERS' BATTLE

The success of our present and future plans of medical practice will depend in the final analysis on the interest and activity of the officers, the committees, and the members in each county society—*From the annual report of LeRoy A Wilkes, M D, executive officer, Medical Society of New Jersey*

MAN-MADE SUNSTROKE FOR TB BUGS

Artificial sunlight can swiftly clear the air of tuberculosis germs floating about in it Ultra violet rays, within three seconds, killed 96 per cent of the tuberculosis germs suspended in the air in experiments reported by Drs William I Wells and Max B Lurie, University of Pennsylvania

HURT FASTER, HEAL FASTER

British and French medical journals report that wounds suffered by Allied troops are cleaner and infections fewer than in the World War It is believed that this is due to the greater velocity of the German missiles which "go clear through the body, carrying fewer particles of tissue with them"

THE BIG-BORE SPEAKER

Professor (who has spoken for two hours) "I shall not keep you much longer I am afraid I have spoken at rather great length There is no clock in the room, and I must apologize for not having a watch with me"

Student "There's a calendar behind you, doctor"—*Medical World*

Improvements

Herkimer Memorial Hospital plans to build a new wing to add 20 to 25 beds to the present 30

The Bassett Hospital at Cooperstown has installed new x-ray equipment

About \$25,000 was raised at the annual dinner of the Israel Zion Hospital of Brooklyn to resume construction of an additional building started in 1936 and postponed for lack of funds

Plans for a new New York City cancer hospital on a site at 163rd Street and Fort Washington Avenue were advanced on December 5 when the Board of Estimate referred an agreement between the city, Columbia University, and Presbyterian Hospital to the City Planning Commission for a report

Under the agreement the trustees of the university and the hospital would convey the two-and-a-half acre site, valued at \$750,000, to the city without charge. Dr Willard C Rappleye, hospitals commissioner, told the board that a ten-story institution with 315 beds could

At Albany, New York, November 6, there was organized the Northeastern Society of Anesthesiology, consisting of physicians interested in this subject from Northeastern New York and the Western New England States. The officers

be built there at a cost of \$2,650,000, adding the \$600,000 already had been authorized for plans and specifications

He estimated that the building could be completed in 1942. Completion of the new building would permit the city to tear down the Cancer Institute on Welfare Island and the Cancer Clinic at 124 East Fifty-ninth Street

The Methodist Episcopal Hospital, on Sixth Street, Seventh to Eighth Avenues, Brooklyn, is to build an eight-story addition alongside its present structure at a prospective cost of \$950,000

Cornerstones of the two principal buildings of the new Hillside Hospital, 264th Street and Union Turnpike, near Little Neck, Queens, New York, were laid on November 17 before 1,000 spectators by Lucius N Lattauer, Governor and New York philanthropist, and Henry Kaufmann, of Pittsburgh, the two principal donors to the fund for construction of the hospital

The cornerstone of the new \$200,000 addition to Faxon Hospital, Utica, was laid on December 15

selected were Dr F A D Alexander, Albany chairman, Dr W J Martin, Albany, secretary, treasurer, Dr W M Moriarty, Saratoga Springs, chairman of program committee. The Society will meet once monthly in Albany

POINT OF ATTACK FOR THE POINT OF A TACK

A story is recalled of the hillbilly sitting underneath the tree and howling with pain. A sympathetic passerby watched for a few minutes and then said, "What is the matter?"

The hillbilly replied, "I'm sitting on a tack."

Almost every doctor of medicine is howling with rage because the quacks use the term "doctor." There are none of the barnacles on the ship of Healing Arts who dare to use the degree M.D.

Why not move off the tack?

Use "M.D." on your door and stationery!—*J Michigan M Soc*

DELINQUENT PATIENT IS PROSECUTED

Recently, an uncooperative patient with earl syphilis was brought before Judge William N Edwards, of Rye, on the charge of failure to obey the lawful order of a health officer. Although directed to attend clinic weekly for treatment, the patient had not appeared at clinic for more than a month. The defendant was found guilty, charged and sentenced to one year imprisonment and \$2,000 fine (the maximum under the law), after which sentence was suspended provided the patient attended clinics as ordered. In case of failure to attend the sentence will be imposed.—*Westchester's Health*

PROTECT THE FAMILIES

The individual physician must protect the families in his care and through them the community by urging physical examination of domestic employees. Repeated emphasis on the necessity of this should result in the earlier diagnosis of tuberculosis and in the prevention of exposure to infants and children from this source of infection. An annual health certificate declaring freedom from syphilis, gonorrhea, and tuberculosis should be the requisite for the position of nursemaid.—*David V Shar, M.D. Journal-Lancel, June 1940*

A WARNING

WAR makes pleasant news for the tubercle bacillus. As the deaths from T.N.T. increase, those from tuberculosis lag not far behind. In the World War all countries showed this phenomenon whether under arms or not. What effect on our efforts to eradicate tuberculosis will these grim months ahead bring forth? Unless we find a way to redouble the offensive against our hidden enemy, the sad story of twenty years ago will be told again and we will find ourselves facing a record of lost ground.—*Kendall Emerson M.D.*

to arrange for periodic conferences between a committee of the state hospital association and representatives of the state and local welfare organizations. Professional advisory committees, composed of leading physicians, dentists, nurses, and hospital administrators, may well be appointed by the welfare department at both the state and local levels. Such committees can help to solve difficulties without undue friction.

Fair play should be the slogan on both sides. Most of these problems can soon be solved if they are approached in this spirit.

A Joyriding Skeleton

THE skeleton in most hospital closets is grinning but well behaved, not at all like Old Bones at Dixon Public Hospital, Dixon, Illinois. It recently took a joyride about the town, as told in *The Modern Hospital*.

For teaching purposes the hospital invested in a new skeleton and lightheartedly decided to discard the old friend that had served faithfully for many years. The janitor was forthwith instructed to take it apart and burn it in the furnace.

Shortly thereafter, the chief of police called to inquire if by chance the hospital was missing a skeleton. "No" was the reply.

"Well, we picked up a drunk who was touring the town with a skeleton on the seat beside him. We thought it might belong to you. Said he picked it up at the city dump."

A grim suspicion entered the superintendent's mind. She summoned the janitor and asked if he had burned the old skeleton. Reluctantly, he admitted that the labor involved in unwiring the joints had seemed an unfair demand upon his time and that he had surreptitiously placed the gentleman's bony framework into the garbage intact.

By way of penance the janitor was sent to police headquarters to retrieve the wandering skeleton, which he sheepishly did. He then burned it under the superintendent's supervision.

Newsy Notes

At least two counties with residents as patients in the Homer Folks Tuberculosis Hospital at Oneonta do not intend to pay the bills being levied against them for the care of these patients, according to reports in the local newspapers. Following a conference with Chenango County officials, who said Chenango County does not intend to pay any bills of the Oneonta institution, Madison supervisors voted unanimously on December 2 to follow the same procedure.

Both counties will cooperate in defending litigation which the state is expected to bring in an effort to collect the hospitals' bills. Madison County's bill is approximately \$81,000 and Chenango County's about \$45,000. Delaware County has been billed for \$50,000, and a committee has been appointed to consider the claim.

The suburban villages of Lakewood, Falconer, and Celeron, which have received free public

health laboratory service from the municipal laboratory at Jamestown for many years, soon will be required to pay the full cost of such service as a result of action taken by the board of municipal laboratory managers at Jamestown General Hospital on November 19.

The action came as a direct result of the refusal by the Chautauqua County Board of Supervisors to take action on a proposal recommended by the county medical society for providing laboratory service for all villages and towns, which, until now, have used the facilities of Jamestown and Dunkirk laboratories without charge.

The service which the Jamestown Laboratory has been providing for its neighboring villages includes routine examinations of water and milk supplies, regarded as a prime safeguard of the public health.

A new private hospital, the Sunnyside Sanitarium, to take 30 to 35 patients, has been opened on Staten Island. The medical staff consists chiefly of local physicians.

The Gowanda State Hospital Employees Federal Credit Union has lent over \$105,000 to its members since its organization five years ago, says its official report. The group has saved \$51,540, paid dividends of \$2,468 to themselves, and saved interest rates and finance charges estimated at \$10,050.

Mobile lending libraries were presented to the Olean General Hospital and to St. Francis Hospital by the Junior Group of the Daughters of the American Revolution and the Rotary Women's Club on November 30.

Rotary furnished books and magazines and the Junior D. A. R. provided the carts. Members of the latter organization operate the libraries at each hospital two afternoons a week.

The Board of Managers of the Oneida County Hospital have voted not to admit reporters to their meetings, except by invitation.

Ellis Hospital at Schenectady has arranged to have electric current supplied from two independent sources. The switchboard has automatic changeover equipment that will operate immediately upon the interruption of either source of supply, transferring the entire hospital load to the remaining service.

Doctors on the staff at Sterling Public Hospital, Sterling, Illinois, have voted to fine themselves for late or incomplete records. The superintendent reports the procrastinators to a staff officer and the names are read at the monthly staff meeting.

Woman's Auxiliary

To the Medical Society of the State of New York

1 message from our program chairman—

The program of the Woman's Auxiliary to the State Medical Society offers its members a fine opportunity for service to our sponsoring Society. Founded as our organization is upon the principle that an informed group of women could (1) interpret the aims of the medical profession to other organizations interested in health education, (2) that they could assist in entertaining at the sessions of the American Medical Association, (3) that they could promote friendliness among families of the medical profession, and (4) that they could carry on work approved by the Advisory Council—the Woman's Auxiliary has already earned its right to existence as an organization. The program has three aspects—educational, social, and economic.

Under the first heading, educational, comes the planning in each county society of a series of meetings at which topics of general interest in the health field may be discussed by qualified speakers so that our members may be equipped with the information so often sought from physicians' wives, or, if not fully informed, may at least refer the applicant to the proper source for the information. The choice of topics for the monthly meeting is very broad but should always be dictated by the specific needs and interests of the community. Approval of any major project should, of course, be secured from the county medical society. Speakers may usually be secured from the county society, and each county auxiliary should keep on file the list of speakers and their addresses. Following the formal presentation a general discussion will prove beneficial but this should always be arranged with the speaker before the program begins. The educational purposes may also be carried on by study groups formed of members who are prepared to lead informal discussions on selected topics. This method may also be applied to the study of the economic aspect of our program. Topics such as health insurance and socialized medicine will awaken the interest of many otherwise inactive members, and make them aware of the threat to the economic security of the medical profession and the danger to the public of the resultant impairment in public health services.

The social aspect of the organization has required very little aid in producing the desired

friendliness among physicians' families and in assisting at the entertainment at medical meetings. To supplement the usual formal program by an hour of sociability over a cup of tea—although originally not thought important or even desirable—has been found quite constructive in producing an atmosphere of cordial goodwill and friendly understanding. The fruits of these contacts will be evident when the county medical society includes the ladies in the invitation to their annual dinner, or when the next District Branch Meeting brings doctors and their wives together. A great deal of variation is possible in the planning of the social program and each county can best decide its own particular activities. No program service could be complete without including some specific form of social work such as an active interest in, and regular contributions to, the Physicians' Home, or help rendered to the local physicians' families in need of temporary assistance. In the present world crisis Red Cross activities should find a definite place in our planned program. In cooperation with the Public Health and Public Relations Committee a survey may be made of the organizations in which the members participate, a mailing list may be obtained from each of these and when health meetings of interest to the public are planned, notices may be sent to all persons on the various lists and their attendance urged. Cooperation with such groups as the Tuberculosis and Public Health Association, the Society for the Control of Cancer and the American Red Cross will be found of mutual benefit.

This outline of what our program may include should not be considered mandatory in any respect. Flexibility is a most desirable attribute in any plan of work. Cooperation with the Public Health and Public Relations Committee and the Legislation Committee of the State Medical Society will often indicate variation from the plan laid out at the beginning of the year. We must ever be on the alert to embrace any opportunity to assist our State Medical Society through whom we obtain membership in the Auxiliary, by promoting their aims and interests with all the force at our command.

(MRS ALBERT M) ISABEL C BELL
State Program Chairman

County News

Albany Since the last report the auxiliary has been very busy. A bridge tea and bake sale attended by ninety-five physicians' wives started the activities for the year. Dr. Robert Cunningham, professor and dean of Albany Medical College, addressed the group on medical education. He told of the important changes that have taken place in medicine and the need for doctors' wives to know about them. A reception in honor of Dr. and Mrs. Cunningham followed. Wives of the faculty members were invited as special guests. In the

receiving line were Mrs. Louis Hocker, membership chairman, Mrs. William Fitzgerald, president-elect, and Mrs. A. L. Madden, president. For the November meeting Mrs. J. S. Lyons, program chairman, arranged for Dr. Louis Bauer, Hempstead, Long Island, to speak on the medical preparedness policy. Dr. Bauer is speaker of the House of Delegates and a member of the Preparedness Council of the State Society. Albany was fortunate in having a man so well qualified to present a topic of such vital importance. On December 10 a rare treat was

THE THIRD ANNUAL CONGRESS ON INDUSTRIAL HEALTH

January 13 and 14, Palmer House, Chicago

Topics and speakers are as follows

OPENING SESSION, MONDAY, 9 45 A.M.

Report of the Council on Industrial Health

STANLEY J SEEGER, M D, Chairman, Milwaukee

The Physician in Industry and National Defense

IRVIN ABELL, M D, Chairman, Health and Medical Committee in the Council of National Defense, Louisville, Ky

Current Needs in Industrial Hygiene Research

PHILIP DRINKER, Professor of Industrial Hygiene, Harvard University, Boston

The Special Nature of Industrial Practice

C O SAPPINGTON, M D, Chicago

Disability Evaluation in Silicosis

J L BLAISDELL, M D, Porcupine Clinic for Silicosis Research, St Mary's Hospital, Timmins, Ontario

Red Lacquer Room

MONDAY, 2 P M

HAND INJURIES

Anatomic Diagnosis of Injuries of the Hand

JAMES M WINFIELD, M D, Associate Professor of Surgery, Wayne University College of Medicine, Detroit

Treatment of Superficial Hand Injuries and Burns

HARVEY S ALLEN, M D, Chicago

Division of the Nerves and Tendons of the Hand

MICHAEL MASON, M D, Chicago

Importance of Purposeful Splinting Following Injuries of the Hand

HENRY C MARBLE, M D, Boston

Prevention and Treatment of Hand Infections

SUMNER L KOCH, M D, Chicago

Red Lacquer Room

MONDAY, 2 30 P M

AVAILABILITY OF TRAINED INDUSTRIAL HEALTH PERSONNEL

The Trained Industrial Nurse

RUTH HOULTON, R N, Secretary, Industrial Nursing Section, National Organization for Public Health Nursing, New York

The Industrial Hygiene Engineer

(Speaker to be announced)

The Safety Engineer

W H CAMERON, Managing Director, National Safety Council, Inc, Chicago

The Medical Industrial Hygienist

PAUL A NEAL, M D, Chief of the Division of Industrial Hygiene, National Institute of Health, U S Public Health Service, Bethesda, Md

The Physician in Industry

ROBERT T LEIGH, M D, University of California, Berkeley, Cal

Room 8

MONDAY, 6 30 P M

An informal dinner and round table discussion intended primarily for state and county medical society committees on industrial health will be held. The subject matter for discussion will include problems of organization and plans for future activity

TUESDAY, 9 30 A M

Employment of the Physically Handicapped

D L LYNCH, M D, President, American Association of Industrial Physicians and Surgeons, Boston

Ageing as a Problem of Industrial Health

EDWARD J STIEGLITZ, M D, Research Associate in Gerontology, National Institute of Health, U S Public Health Service, Bethesda, Md

ACUTE RESPIRATORY DISEASE IN INDUSTRY

Incidence and Costs of Acute Respiratory Disease in Industry

ANTHONY J LANZA, M D, Assistant Medical Director, Metropolitan Life Insurance Company, New York

Respiratory Disease and Air Conditioning

CAREY P MCCORD, M D, Chairman, Committee on Air Conditioning of the American Medical Association, Detroit

The Role of the Physician in Industry in the Control of Acute Respiratory Disease

GEORGE M PIERSOL, M D, Philadelphia

Red Lacquer Room

TUESDAY, 2 P M

INDUSTRIAL OPHTHALMOLOGY

Economic Importance of Visual Disability in Industry

LEONARD GREENBURG, M D, Chairman, Industrial Advisory Committee of the National Society for the Prevention of Blindness, New York

Essentials of First Aid and Later Management of Industrial Eye Injuries

SYDNEY WALKER, JR, M D, Chicago

Detection and Control of Defective Vision in Industry

ARTHUR M CULLER, M D, Dayton, Ohio

Protective Equipment for Eyes in Industry

THOMAS D ALLEN, M D, Associate Clinical Professor of Ophthalmology at Rush Medical College, Chicago

HENRY F CARMAN, M D, San Francisco

Red Lacquer Room

WEDNESDAY, JANUARY 15

On the day following the congress, the Chicago Medical Society will conduct clinics illustrating practical problems in industrial medicine, industrial hygiene, and traumatic surgery

On the same day the Chicago Medical Society will hold a dinner and evening meeting on the relationship of the private practitioner to the industrial health movement. The program will be

Industrial Health—A Medical Opportunity

STANLEY J SEEGER, M D, Chairman, Council on Industrial Health, American Medical Association, Milwaukee

Medical Service for the Small Plant

ANTHONY J LANZA, M D, New York

The Control of Syphilis in Industry

HAROLD A VONACHEN, M D, Peoria, Ill

INSTITUTE ON RADIOLOGY
Syracuse University College of Medicine
Syracuse, New York

Saturday, January 18, 1941

Presented under the auspices of Central New York Roentgen Ray Society; Medical Society of the State of New York, Syracuse University College of Medicine, Division of Cancer Control of the New York State Department of Health.

P R O G R A M

January 18, 1941

Syracuse University College of Medicine, Syracuse

Meeting called to order at 1 30 p m by

Albert Lenz, M.D., President

Central New York Roentgen Ray Society

Opening Remarks

James M. Flynn, M.D., President

Medical Society of the State of New York

Chairman of the Meeting

Herman G. Weiskotten, M.D., Dean

Syracuse University College of Medicine

- 1 45 p.m. "Physics of Radiation for the Radiologist"
Edith H. Quimby, Sc.D., Associate Physicist
Memorial Hospital, New York City
- 2 30 p.m. "Roentgenological Aspects of Brain Tumors: Diagnosis and Treatment"
Merrill C. Sosman, M.D., Roentgenologist
Peter Bent Brigham Hospital, Boston, Mass.
- 3 15 p.m. "Indications and Results of Roentgen Therapy"
Ursus V. Portmann, M.D., Radiation Therapist
Cleveland Clinic, Cleveland, Ohio
- 4 00 p.m. "Radiosensitivity of Tumors"
Fred W. Stewart, M.D., Pathologist
Memorial Hospital, New York City
- 4 45 p.m. "The Cyclotron"
Stafford L. Warren, M.D., Chief Radiologist
Strong Memorial Hospital, Rochester, New York
- Discussion conducted by Louis C. Kress, M.D., Director, Division of Cancer Control,
New York State Department of Health

DINNER MEETING (Informal)

7 00 p.m. Small Ballroom, Hotel Syracuse, Syracuse, New York

Toastmaster—James M. Flynn, M.D.

Introduction of Speaker by

Edward S. Godfrey, Jr., M.D., Commissioner

New York State Department of Health

Speaker

R. R. Spencer, M.D., Assistant Chief, National Cancer Institute, United States Public Health Service

Local Committee on Arrangements

Carlton F. Potter, M.D., Chairman

Donald S. Childs, M.D., Lucas S. Henry, M.D., Foster C. Rulison, M.D.

While the Institute is planned especially for radiologists, all physicians in the state are cordially invited to attend. The price of the dinner is \$2.00. No other fees will be charged. The sponsoring agencies are very anxious to know how many plan to attend the afternoon session and how many will be at the dinner. Reservations should be addressed to

O. W. H. Mitchell, M.D., Chairman

Council Committee on Public Health and Education

Medical Society of the State of New York

428 Greenwood Place, Syracuse, New York

afforded the members of Albany, Columbia, Saratoga, Rensselaer, and Schenectady counties with an opportunity to hear Dr Peter Irving of New York City, secretary and general manager of the New York State Medical Society and the editor of the NEW YORK STATE JOURNAL OF MEDICINE. He stressed three subjects of the utmost importance at the moment to the State Society and the sixty-one component county medical societies: (1) The Revision of the School Health Program for the State of New York, (2) Medical Care of the Indigent, the Near Indigent, and also the Lower Income Group just above, and (3) Medical Preparedness. Considerable work is being done by the State Society in all these phases. Dr Irving advised physicians' wives to be on the alert to inform the lay people on "what we think can and should be done to achieve the best results in these fields." The audience was greatly impressed by the delightful manner in which Dr Irving presented his topic which is of keen interest to auxiliary members.

Queens Mrs Michael Schultz of Hollis, Long Island, was named president, and Mrs William Godfrey of Flushing, president-elect at a meeting of the woman's auxiliary in the Medical Building, Forest Hills. Mrs Schultz succeeds Mrs R H Murphy. Other officers elected and installed with Mrs Schultz at a reception held by the Auxiliary in the Medical Building on December 14, include Mrs J M Dobbins, first vice-president, Mrs P B Shuey, recording secretary, Mrs Howard Meail, treasurer, Mrs Harold Foster, assistant treasurer, Mrs T M d'Angelo, historian. District representatives Mesdames Edward Steiner, Giuseppe D'Andrea, J Gibson Hall, W J Lynch, Hillard Bresky, Charles Levin, Geo Jantzen, Frank Mazzola. Mrs Harry P Mencken was chairman of the

nominating committee. Following the installation there was a musical program given by the doctors' orchestra. Mrs. Paul B Schuey is chairman of the Installation Committee. Mrs. Murphy at the meeting on November 26 announced that she would hold a tea at the Medical Building for the outgoing and incoming officers on December 3.

Washington It is always a pleasure to represent a new county for "our page." Real progress was made by the Washington County Auxiliary this fall. The first regular meeting convened at the home of Mrs Edward V Farrell, Whitehall. The officers selected for the year were president, Mrs Irvin V Decker, Sailem, vice-president, Mrs E V Farrell, Whitehall, secretary, Mrs Wallace F MacNaughton, Ft Edward, treasurer, Mrs Roy L Borrowman, Ft Edward. Plans were made at the first executive board meeting at the home of Mrs MacNaughton to broaden the scope and activity of the auxiliary, to have diversified programs, sponsoring outstanding speakers and to hold a luncheon or dinner meeting annually. Due to the long distance between towns in Washington County, as is the difficulty in so many upstate organizations, four meetings will be held yearly. On December 10, Mrs W MacNaughton was hostess to sixteen members and three new members for a social and business meeting. Mrs I Decker appointed Mrs Thomas C Healy to compile material from medical magazines, especially *Hygeia* and the *Auxiliary Bulletin*, in this way creating the interest of doctors' wives in medical literature. At the social hour Mrs D M Vickers sang and was accompanied by Mrs G H Hiney of Cambridge—thus concluding an afternoon which made everybody feel happy to be one of this large organization.

DON'T FORGET OUR NATIONAL BULLETIN

It is not too late to subscribe!

AWARDS FOR OBSERVATIONS ON EPILEPSY

Two annual awards of \$100 each are offered by the Laymen's League against Epilepsy for the best original unpublished observations or investigations bearing on the subject of epilepsy. One of these is for work done in a state epileptic colony or mental hospital, the other is for work done elsewhere. Since one object of the award is the encouragement of junior workers, the committee will take into consideration the facilities of the authors, clinical as well as laboratory studies will be welcomed. Awards will be made by a committee of three, composed of the president of the American League against Epilepsy, the chair-

man of the Section on Convulsive Disorders of the American Psychiatric Association, and a third physician chosen by the officers of the Laymen's League against Epilepsy. It is hoped that winning contributions will be presented before the annual joint scientific session of the first two of these organizations. At the discretion of the committee awards may be divided or postponed.

Additional information can be obtained from the secretary of the Laymen's League against Epilepsy, Mrs N Bond Fleming, 25 Shattuck Street, Boston.

Rastas Sambo does yo' all know why dere am such an affinity 'tween a colored man an' a chicken?"

Sambo "Must be 'cause one am descended from Ham an' de odder from eggs"—*Pathfinder*

A man reviving from an anesthetic was being very sentimental. The wife nearby said to the nurse "I have not heard him talk like that since our honeymoon, where do you buy the dope?"—*The Doctor and Old Quarterly*

nomics of the American Medical Association Octavo of 185 pages Chicago, American Medical Association, 1939 Paper

It would stretch the imagination of a social planner to devise any scheme for the organized payment for medical services that is not described in this publication. Several hundred plans for medical care of the indigent involving governmental support and medical society management are explained.

The House of Delegates of the American Medical Association has endorsed cash indemnity prepayment plans but has not sought to prohibit any of its component societies from cooperating with or organizing other types of prepayment for medical service provided their character is not such as to render it impossible to give good medical service.

The number and variety of the plans for medical services—operating and proposed, postpayment and prepayment, service and cash, sponsored by a medical society and other organization—give proof of the efforts that are being made to supplement the private practice of medicine, and indicate a desire to discover, by social experimentation a solution of local medical problems.

Handbook of Bacteriology For Students and Practitioners of Medicine By Joseph W. Bigger, M.D. Fifth edition Octavo of 466 pages illustrated Baltimore, Williams & Wilkins Co., 1939 Cloth, \$4.25

The new edition of this excellent handbook contains short but quite complete descriptions of the pathogenic microorganisms. The sections on immunology are also adequate for the purpose for which they are intended. By elimination of most of the controversial material and burdensome data the author has succeeded in compiling a volume which very well meets the needs of the general practitioner.

ALVIN HOLLANDER

A Synopsis of Surgical Anatomy By Alexander L. McGregor, F.R.C.S. Fourth edition. Duodecimo of 664 pages, illustrated Baltimore Williams & Wilkins Co., 1939 Cloth, \$6.00

This small book contains a wealth of useful information for surgical diagnosis and treatment. In a concise manner and with an abundance of excellent diagrams it covers the field of normal and abnormal anatomy as the practitioner must know it.

For quick reference it is an excellent book to have at hand.

EDWARD P. DUNN

Fundamentals of Biochemistry in Relation to Human Physiology By T. R. Parsons M.A. Sixth edition. Duodecimo of 461 pages, illustrated. Baltimore, William Wood & Co. 1939 Cloth, \$3.00

The fact that this book has reached its sixth edition, coupled with the fact that the fifth edition had to be reprinted twice, is sufficient evidence of its popularity and usefulness. The reason for this is immediately perceived on reading it. A treatise on chemistry is expected to be dry as dust and studying it a tiresome mental exercise. Instead this book reads almost like a novel and affords mental relaxation. Particularly interesting are the little quotations at the

head of each chapter. The author quotes not only from scientific writers but lines from Shakespeare, Nietzsche, Gray, and St. Paul are found which apply to the subject under discussion. This serves to connect a supposedly pure science with philosophy and religion—indeed with life and living.

A new chapter on sterols is particularly timely and it will probably be greatly expanded in future editions.

All in all it is a welcome revisit of an old friend
BENJAMIN DAVIDSON

Argyria The Pharmacology of Silver By William R. Hill, M.D., and Donald M. Pillsbury, M.D. Octavo of 172 pages Baltimore Williams & Wilkins Co., 1939 Cloth, \$2.50

The authors have covered the subject in a thorough and comprehensive manner. The bibliography is exhaustive—601 references are listed. They point out the necessity for more enlightenment of physicians and pharmacists regarding this complication of silver therapy. The public, too, should be warned on the labels of containers of silver compounds dispensed on prescription or taken as self-medication.

CHARLES SOLOMON

Psychiatry for Nurses. By Louis J. Karnosh M.D., and Edith B. Gage, R.N. Octavo of 327 pages illustrated St. Louis, C. V. Mosby Co. 1940 Cloth, \$2.75

This is an elementary textbook for nurses which tends to present in a simple and concise though adequate manner, the salient points of psychiatry so that the pupil nurse may get an adequate appraisal of the facts in the nursing of mentally sick patients. It is written with the view of enabling the nurse to familiarize herself quickly with the symptoms and treatment of the more common psychoses. It tends to follow the psychobiologic school of psychiatry more than any other school. A special chapter discusses shock therapy in mental diseases, and special chapters are devoted to medicolegal aspects of psychiatry and to mental hygiene.

It is a good book that recommends itself to the average pupil nurse.

IRVING J. SANDS

The New International Clinics Original Contributions, Clinics, and Evaluated Reviews of Current Advances in the Medical Arts. Edited by George M. Piersol, M.D. Volume I, New Series Three. Octavo of 319 pages, illustrated Philadelphia, J. B. Lippincott Co., 1940 Cloth \$3.00

The latest issue of *The New International Clinics* contains as usual many valuable clinical articles. The Review of Recent Progress is that by Cantarow in the field of the vitamins. There is a symposium from the University of Pennsylvania in which the most provocative paper is that by Fitts-Hugh on "Precordial Migraine." In this issue, too, is the first half of an excellent comprehensive review of jaundice by Held and Goldbloom.

MILTON PLOTZ

Trial of Field and Gray Edited by Winifred Duke. Octavo of 302 pages illustrated London, William Hodge & Co. 86 Hatton Garden, 1939 Cloth, 10/6

Books

Books for review should be sent to the Book Review Department at 1313 Bedford Avenue, Brooklyn N Y. Acknowledgment of receipt will be made in these columns and deemed sufficient notification. Selection for review will be based on merit and the interest to our readers.

The Poison Trail. By William F Boos, M D Octavo of 380 pages New York, Hale, Cushman & Flint through the American Can Company, 1939 Cloth, \$3 00

This volume of reminiscences of a Massachusetts' toxicologist contains much popularized information about poisons It may prove of interest to amateur toxicologists and aid readers of stories of crime detection Despite a supplement containing a description of various analyses, there is little to interest the scientist The style is sensational, sometimes interesting, and always devoid of distinction

MILTON PLOTZ

It Is Your Life Keep Healthy, Stay Young, Live Long By Max M Rosenberg, M D Octavo of 450 pages, illustrated New York, The Scholastic Book Press, 1940 Cloth, \$2 50

This is a book on health written for the laity by a physician Thus it has a better background of medical information than the many volumes on this subject written by physical directors, nurses, and what have you

The subjects covered in this book are legion but for the most part are topics on which the people should be informed Generally speaking, the subject matter is presented in simple language, at least, where the author evidently feels that he is too technical, an attempt is made to explain the points more clearly

Emergency and simple measures to be used for ordinary ailments are described but beyond this point the services of a physician are urged

A E SHIPLEY

The Foot and Ankle Their Injuries, Diseases, Deformities and Disabilities By Philip Lewin, M D Octavo of 620 pages, illustrated Philadelphia, Lea & Febiger, 1940 Cloth, \$9 00

A book of some six hundred pages devoted entirely to the human foot and covers diseases, injuries, deformities, and disabilities In a word it is a comprehensive study of the foot and fills a long-felt need in medical literature

It is well written, the illustrations are ample, and the bibliography is large There is nothing quite like it in the literature, and it will become a standard reference book on the subject

Dr Philip Lewin is to be congratulated on presenting to the medical profession so valuable a contribution

JA C RUSHMORE

Fractures and Other Bone and Joint Injuries By R. Watson-Jones, F R C S Octavo of 723 pages, illustrated Baltimore, Williams & Wilkins Co, 1940 Cloth, \$13 50

The author has had a large experience in the treatment of fractures and allied injuries As a result of this wide experience, he has developed a personal technic and methods of handling these injuries Most of them are simple and can be easily followed by the average surgeon Although the book is essentially devoted to the

methods devised by the author, there are numerous instances where he advocates the technic devised by others which he has found to be efficient It is one of the best books published on the subject It is well illustrated by excellent drawings and photographs and is recommended for all who do traumatic surgery, whether of a minor or major character

J B L'EPISCORO

Clinical Practice in Infectious Diseases. For Students, Practitioners and Medical Officers By E H R. Harries M D, and M Mitman, M D Octavo of 468 pages, illustrated Baltimore, Williams & Wilkins Co, 1940 Cloth, \$6 00

So many advances have been made in the field of the acute infectious diseases within recent years that there is a place for a textbook, like this, which appears comprehensive and modern in all respects and which certainly is of timely interest

It is novel to have described, in one volume practically the entire group of the acute infectious diseases or fevers which are apt to be encountered even in time of war This is a departure from the usual method but is beyond question a welcome one and should receive the commendation it deserves The authors, in giving a modern clinical description of these diseases and of their care and treatment, provide us also from their own personal experiences with a critical commentary particularly with regard to the practical application of certain of the more important advances made

In the first eleven chapters of the book, certain general aspects of the acute infectious diseases are covered including infection and resistance, hypersensitivity and allergy, transmission and diagnosis, epidemiology and control and, finally, general management and diet The following chapters not only describe diphtheria, the exanthemas, whooping cough, and mumps but also glandular fever, hemolytic streptococcal infections, fusospirochloosis, the acute infectious diseases of the nervous system, cerebrospinal fever, acute poliomyelitis, epidemic encephalitis, as well as certain ingestion diseases, dysentery, enteric fever, undulant fever, and psittacosis, infectious jaundice influenza, tetanus, and epidemic louse-borne diseases Finally, there is a chapter on control of infectious diseases in hospitals

Originality is also shown in the type of illustration, and a logical method of presentation, especially for teaching, is evident throughout the book In this volume the practitioner, the public health officer, and the student will find a most useful text containing a wealth of information concerning the epidemic infectious diseases or fevers

JOSEPH C REGAN

Organized Payments for Medical Services A Report Prepared by Bureau of Medical Eco-

nomics of the American Medical Association Octavo of 185 pages Chicago, American Medical Association, 1939 Paper

It would stretch the imagination of a social planner to devise any scheme for the organized payment for medical services that is not described in this publication Several hundred plans for medical care of the indigent involving governmental support and medical society management are explained

The House of Delegates of the American Medical Association has endorsed cash indemnity prepayment plans but has not sought to prohibit any of its component societies from cooperating with or organizing other types of prepayment for medical service provided their character is not such as to render it impossible to give good medical service

The number and variety of the plans for medical services—operating and proposed, postpayment and prepayment, service and cash, sponsored by a medical society and other organization—give proof of the efforts that are being made to supplement the private practice of medicine, and indicate a desire to discover, by social experimentation, a solution of local medical problems

Handbook of Bacteriology For Students and Practitioners of Medicine By Joseph W Bigger, M D Fifth edition Octavo of 466 pages illustrated Baltimore, Williams & Wilkins Co, 1939 Cloth, \$4 25

The new edition of this excellent handbook contains short but quite complete descriptions of the pathogenic microorganisms The sections on immunology are also adequate for the purpose for which they are intended By elimination of most of the controversial material and burdensome data the author has succeeded in compiling a volume which very well meets the needs of the general practitioner

ALVIN HOLLANDER

A Synopsis of Surgical Anatomy By Alexander L McGregor, F.R.C.S Fourth edition Duodecimo of 664 pages, illustrated Baltimore, Williams & Wilkins Co, 1939 Cloth, \$6 00

This small book contains a wealth of useful information for surgical diagnosis and treatment In a concise manner and with an abundance of excellent diagrams it covers the field of normal and abnormal anatomy as the practitioner must know it

For quick reference it is an excellent book to have at hand

EDWARD P DUNN

Fundamentals of Biochemistry in Relation to Human Physiology By T R Parsons, M A Sixth edition Duodecimo of 461 pages, illustrated Baltimore, William Wood & Co, 1939 Cloth, \$3 00

The fact that this book has reached its sixth edition, coupled with the fact that the fifth edition had to be reprinted twice, is sufficient evidence of its popularity and usefulness The reason for this is immediately perceived on reading it A treatise on chemistry is expected to be dry as dust and studying it a tiresome mental exercise Instead this book reads almost like a novel and affords mental relaxation Particularly interesting are the little quotations at the

head of each chapter The author quotes not only from scientific writers but lines from Shakespeare, Nietzsche, Gray, and St Paul are found which apply to the subject under discussion This serves to connect a supposedly pure science with philosophy and religion—indeed with life and living

A new chapter on sterols is particularly timely, and it will probably be greatly expanded in future editions

All in all it is a welcome revisit of an old friend
BENJAMIN DAVIDSON

Argyria The Pharmacology of Silver By William R. Hill, M D, and Donald M Pillsbury, M D Octavo of 172 pages Baltimore Williams & Wilkins Co, 1939 Cloth, \$2 50

The authors have covered the subject in a thorough and comprehensive manner The bibliography is exhaustive—601 references are listed They point out the necessity for more enlightenment of physicians and pharmacists regarding this complication of silver therapy The public too, should be warned on the labels of containers of silver compounds dispensed on prescription or taken as self-medication

CHARLES SOLOMON

Psychiatry for Nurses By Louis J Karnosh M D, and Edith B Gage, R.N Octavo of 327 pages illustrated St Louis, C V Mosby Co, 1940 Cloth, \$2 75

This is an elementary textbook for nurses which tends to present in a simple and concise though adequate manner, the salient points of psychiatry so that the pupil nurse may get an adequate appraisal of the facts in the nursing of mentally sick patients It is written with the view of enabling the nurse to familiarize herself quickly with the symptoms and treatment of the more common psychoses It tends to follow the psychobiologic school of psychiatry more than any other school A special chapter discusses shock therapy in mental diseases, and special chapters are devoted to medicolegal aspects of psychiatry and to mental hygiene

It is a good book that recommends itself to the average pupil nurse

IRVING J SANDS

The New International Clinics Original Contributions, Clinics, and Evaluated Reviews of Current Advances in the Medical Arts Edited by George M Piersol, M D Volume I, New Series Three Octavo of 319 pages, illustrated Philadelphia, J B Lippincott Co, 1940 Cloth \$3 00

The latest issue of *The New International Clinics* contains as usual many valuable clinical articles The Review of Recent Progress is that by Cantarow in the field of the vitamins There is a symposium from the University of Pennsylvania in which the most provocative paper is that by Fitts-Hugh on "Precordial Migraine" In this issue, too, is the first half of an excellent comprehensive review of jaundice by Held and Goldbloom

MILTON PLOTZ

Trial of Field and Gray Edited by Winifred Duke Octavo of 302 pages, illustrated London, William Hodge & Co, 86 Hatton Garden 1939 Cloth 10/6

Among the notable British trial series, that of Field and Gray represents expediency and thoroughness with which British criminal subjects are brought to justice.

The book has been edited by an expert in descriptive sequence and covers the period from the date that the homicide was committed to the time of apprehension of the defendants and thence to the conviction of the latter by circumstantial evidence.

This case is worthy of publication because of the personalities of the counsel and that of the presiding justice, and also because of the pathetic attempts of the accused to build up an alibi.

This volume will be of interest to those who appreciate jurisprudence in medicine.

S INGRAM HYKIN

Population, Race and Eugenics By Morris Siegel, M D. Duodecimo of 206 pages. Hamilton, Ontario, The Author, 546 Barton Street, E., 1939. Cloth, \$3.00.

This small volume is interesting and educational to all, whether they know little or much about the subject of eugenics. Most people know too little about it, and those who give a few hours to the study of this book will find themselves amply repaid.

The author divides his work into two parts: positive eugenics and negative eugenics. The section on positive eugenics considers factors and problems as to why the more educated part of our population have fewer offspring than those who are not so well qualified, either mentally or economically, for procreation. The second part of the book deals with the negative side of the question. Here a study is made of what groups of people are not best fitted for parenthood.

What shall be done about this interesting and vital subject? Read the book and let the author give you his views. You will find it worthwhile.

WM SIDNEY SMITH

Observations Made During the Epidemic of Measles on the Faroe Islands in the Year 1846 By Peter Ludwig Panum, M D. (Translated from the Danish by Ada S. Hatcher) with a Biographical Memoir by Julius Jacob Petersen, M D. (Translated from the Danish by Joseph Dimont.) Octavo of 111 pages. Delta Omega Society. Distributed through American Public Health Association, New York, 1940. Cloth.

This book is an English translation by Mrs. Ada Hatcher from the original Danish manuscript by Dr. Peter L. Panum on the epidemiology of measles. A disastrous epidemic of measles occurred on the island of Faeroe in the early part of 1846. Dr. Panum was chosen by the Danish government to check the raging epidemic. This island had been free from any measles invasion since the year 1761. The natural isolation of the island and the restriction of commerce more or less enforced by the Danish government resulted in the exclusion of measles for sixty-five years. But when the epidemic broke out in 1846 it attacked nearly 85 per cent of the population.

Dr. Panum made a thorough study of the origin, mode of introduction, and its high contagiousness. He advocated strict isolation of the attacked and quarantine enforcement. The scattered population and a number of small islands separated by deep and swiftly running

channels made it more favorable for the strict enforcement of the quarantine.

Dr. Panum made a contribution to the science of epidemiology which will remain a classic. The investigations are based upon personal inquiries and accurate investigation of the minutest details. The Delta Omega Society must be heartily congratulated for the perfect selection of this manuscript for the third series of publications of public health classics.

WILLIAM RACHLIN

Cancer in Childhood and a Discussion of Certain Benign Tumors. Edited by Harold W. Dargeon, M D. Quarto of 114 pages, illustrated. St. Louis, C V Mosby, 1940. Cloth, \$3.00.

This is a comprehensive survey of malignant diseases in infants and children contributed to by several authorities and is well illustrated by charts and photographs.

Although cancer is a rare disease in children, it is an important cause of death. The most common tumors in infancy and children are retinal glioma, Wilm's tumor of the kidney, adrenal neurocytoma, and brain tumor (medulloblastoma). The great majority are strictly embryonal. Bone sarcomas in their various forms (especially Ewing's sarcoma) show a distinct predilection for children. Hodgkin's disease, lymphosarcoma, leukemia, and allied conditions run a very malignant course.

This book should be in the possession of every pediatrician.

HARRY MANDELBAUM

Treatment of Some Common Diseases (Medical and Surgical). By Various Authors. Edited by T. Rowland Hill, M D. Octavo of 398 pages, illustrated. Baltimore, Williams & Wilkins Co., 1939. Cloth, \$5.00.

The individual chapters of this volume contain sound, well-written advice on treatment. They are written entirely by members of the staff of the Southend General Hospital in England and are edited by T. Rowland Hill who contributes the sections on anemia and cerebral vascular disease. The book's chief defect is that, as its title implies, only selected topics are touched on, and the book cannot in any sense be considered a textbook of treatment. Its value is, therefore, sharply limited. There is also some failure of proportion in that, for example, the treatment of cardiac infarction is considered in less than a page and over twenty pages are devoted to malignant disease of the pharynx—a chapter, however, which is by far the best of all.

MILTON PLOTZ

Massage and Remedial Exercises in Medical and Surgical Conditions. By Noel M. Tidy. Fourth edition. Octavo of 458 pages, illustrated. Baltimore, Williams & Wilkins Co., 1939. Cloth, \$5.25.

This fourth edition closely follows the third. It reviews fractures, dislocations, and diseases and injuries of the muscular, nervous, and osseous systems, including their aftercare and emergency and physical methods of treatment.

A short description follows each type of injury and the surgical technique to be employed.

The chapters on diseases of the bones and joints, fractures and dislocations are thoroughly discussed.

It is a handy reference book for those prescribing aftercare in orthopedic and traumatic surgery

JOSEPH I NEVINS

Textbook of Public Health (Formerly Hope and Stallybrass) By W M Frazer, M D, and C O Stallybrass, M D Tenth edition Octavo of 504 pages, illustrated Baltimore, Williams and Wilkins Co, 1940 Cloth, \$6 50

The tenth edition of the book that began its career in 1874 gives a comprehensive view of public health as it is organized in England at the present time. Chapter I gives the official organization of public health facilities in the country

The several chapters on environmental sanitation cover the usual subjects found in such textbooks published in this country, but much more elaborate technical detail is given

The space given to such subjects as town planning and housing indicates that such activities occupy an important place in public health administration in England

Hospital administration is also given considerable attention

An interesting feature of the book is the subject matter of the concluding chapter which deals with the medical aspects of civil air defense

F L MOORE

Psychology and Psychotherapy By William Brown, M D Fourth edition Octavo of 260 pages Baltimore Williams & Wilkins Co, 1940 Cloth, \$4 75

This is the fourth edition of a work that first appeared in 1920 It has had a wide circulation and has been generally acknowledged as a practical presentation of the subject of psychotherapy as practiced by a distinguished and experienced psychiatrist He has surveyed the sphere of various theories of psychotherapy and has gathered from each those vital points which he felt could be utilized for the benefit of the patient and has woven it more or less into a method of his own. The book deals with psychotherapy of common neurotic disorders encountered in everyday practice and also with other subjects such as the psychology of peace and war, the psychology of personal influence, the psychoneuroses of war, and the relation of mind to brain

It is a valuable book that is challenging in many ways and will be found useful not only by psychiatrists but also by the general practitioner of medicine It is, therefore, highly recommended for the progressive doctor as well as for the specialist in mental disorders

IRVING J SANDS

The Life and Death Instincts (The Vita and the Fatum) By Arthur N Foxe, M D Octavo of 64 pages New York, Monograph Editions, 1939 Cloth, \$2 00

This very small volume will hardly interest the general practitioner However, it does contain thought-provoking material for the psychoanalyst, even though the latter may not entirely subscribe to the author's deductions

The writer was a psychiatrist in a prison for several years and analyzed many of the inmates according to the Freudian technique

As an interesting attempt to explain the de-

velopment of the "criminoses" from the psychoanalytic point of view it is worth reading

JOSEPH L ABRAMSON

Trattato Di Biotipologia Umana Individuale E Sociale By Professor Nicola Pende Quarto of 665 pages, illustrated Milano, Dottor Francesco Vallardi, 1939 Paper

The author has coined a new word to describe not only the different forms but also the character of each individual. He defines "biotypeology" as that branch of medical science which deals with all the complex vital manifestations (i.e., the anatomic, functional, endocrinologic, and psychologic), from which we can recognize the structural dynamic type of each individual (i.e. the particular characteristics of each individual that differentiate him from another) In other words, "biotypeology" is the science of the architecture and engine of each individual human body and includes the study of individual and racial hereditary factors, the surroundings that influence an individual during the formative years after birth, the action of hormones, vitamins, electrolytes, etc., and the dominating neuro-psychologic factors

The author reviews thoroughly the historical background of the subject, and, although he describes the work of previous students, the book is devoted almost entirely to his own method of study to diagnose the individual biotypes He does this in great detail, giving charts and forms used for the study of each individual from birth to adult life

A considerable portion of the book is devoted to the application of "biotypeology" to clinical medicine and a small portion to "biotypeology" as related to criminology

This book may be called the *biology of man*, in other words the study of his morphology, physiology, and psychology The author is a pioneer in this work, and the book indicates a tremendous amount of effort devoted to the subject It is a valuable addition to the literature and should prove useful as a work of reference

J B L'EPISCOPO

Accepted Foods and Their Nutritional Significance Containing Descriptions of the Products Which Stand Accepted by the Council on Foods of the American Medical Association Octavo of 492 pages Chicago, American Medical Association, 1939 Cloth, \$2 00

Accepted Foods and Their Nutritional Significance contains descriptions and detailed information regarding the chemical composition of more than 3,800 accepted products, together with a discussion of the nutritional significance of each class of foods The book provides also the Council's opinion on many topics in nutrition, dietetics, and the proper advertising of foods

This book will be a welcome reference book for all persons interested in securing authoritative information about foods, especially the processed and fabricated foods which are widely advertised

Epidemiology in Country Practice By William N Pickles, M D Octavo of 110 pages, illustrated. Baltimore, Williams & Wilkins Co, 1939 Cloth, \$2 50

This original little book is the result of the observations made and recorded over many years by Dr Pickles on certain epidemic outbreaks that he has observed in his practice in Wensleydale, England. The primary object of the author is to stimulate other country doctors to keep records of epidemic disease by impressing on them the unique advantages they enjoy in "natural-history" investigation of such diseases, as well as to show how laymen may be interested and may assist in these observations.

The book contains eight chapters and a reference bibliography. In Chapter 4 the commoner diseases are considered, grouped together are influenza, measles, scarlet fever, whooping cough, and mumps. Chapter 5 is devoted to the epidemiologic relationship of chicken pox and shingles. Chapters 7 and 8, dealing with epidemic catarrhal jaundice and epidemic myalgia, respectively, are of much interest and contain epidemiologic and clinical data of importance.

The book shows clearly that the country physician can make significant contributions to our knowledge of epidemiology.

JOSEPH C REGAN

On Oxidation, Fermentation, Vitamins, Health and Disease. By Albert V Szent-Györgyi, M D (Abraham Flexner Lectures Series Number Six.) Octavo of 109 pages. Baltimore, Williams & Wilkins Co., 1939. Cloth, \$2.00.

This volume contains the five Abraham Flexner lectures delivered by Dr Szent-Györgyi at Vanderbilt last year and summarizes his experiments in the field of biologic oxidation during the past fifteen years. The lectures are "Principles of Biological Oxidation," "Respiration of Muscle," "On Fermentation and Intermediary Metabolism," "Vegetable Oxidation," and "Vitamins, Health and Disease." They comprise required reading for all interested in metabolism and the vitamins.

MILTON PLOTZ

Sexual Disorders in the Male. By Kenneth Walker, F.R.C.S., and Eric B. Strauss, D.M. Octavo of 248 pages, illustrated. Baltimore, Williams & Wilkins Co., 1939. Cloth, \$3.00.

Kenneth Walker has rewritten his book with the cooperation of Eric B. Strauss who is a specialist in medical psychology.

Impotence is the main subject, and it is fully and competently covered. Other ailments discussed are premature ejaculations, pollutions, masturbation, homosexuality, and fetishism.

The authors are convinced that the cause of these disorders in the vast majority of cases is functional, and their therapeutic efforts are, therefore, mainly psychologic. They approve of replacement therapy with testosterone if it is indicated. They are critical though of other physical therapeutic techniques, as, for example, of Hühner's silver nitrate installations, of Steinach's vasoligations, and of Lowsley's plication operations.

The reader will be impressed by the vast experience and the sane judgment of the senior author. Because of this the book is in a class by itself and should be read by every medical practitioner.

There is a concise but up-to-date bibliography.
H L WEHRBEIN

Heil Hunger! Health Under Hitler. By Dr Martin Gumpert. Translated from the German by Maurice Samuel. Octavo of 128 pages. New York, Alliance Book Corp., 1940. Cloth, \$1.75.

This isn't just one more anti-Nazi propaganda volume. The author has analyzed national statistics and activities as officially published or gathered from medical statistics appearing in publications published in Germany, apparently without propaganda purposes. His 198 references should enable anyone to make a similar analysis.

It has been assumed by many that the claim of Hitler that the totalitarian state completely regimented leads the people to health and physical strength is a fact. Dr Gumpert states in his foreword that he is revealing to American readers that dictatorship is a sickness which drives all concerned to inevitable physical breakdown and proceeds to show that six years of Nazi rule have achieved

"an increased death-rate, a falling birth-rate, a declining fecundity, an increase in rickets, the physical incapacity of the youth, 90 per cent flat feet, a growing criminality, an increase in drunkenness, a doubling of mental diseases, an increase in venereal diseases, a rise in tuberculosis for man and beast, an increase in epidemics, food poisoning, puerperal fever, an increasing mortality rate in the hospitals, a piling up of fatal accidents, a decline in working capacity, new occupational diseases, injury by compulsory sports, an increase in female labour, undernourishment, a shortage of vitamins, misery among the farmer class, the ruin of science, the decline of military power."

This is a book that will greatly interest the medical reader.

ALEC N THOMSON

The Ophthalmoscope and Studies of the Fundus Oculi in Important Pathological Conditions. Octavo of 32 pages, illustrated. Southbridge, Massachusetts, American Optical Company, 1939. Paper.

The name of no individual author appears on the flyleaf of this pamphlet published by the American Optical Company. The foreword says among other things that the publishers believe it to be an "important contribution to current literature."

The reviewer does not feel that the aim is accomplished. The first few pages are devoted to generalities of doubtful value and little interest. Next follows a few words about the construction of the ophthalmoscope and the results of its use.

Eleven pages, including illustrations, are devoted to a normal and pathologic eyeground features. The illustrations are reproduced so poorly as to be almost valueless.

The reviewer cannot recommend this pamphlet as a worthwhile contribution, and it has no appeal as good advertising matter.

JOHN N EVANS

NEW YORK STATE JOURNAL OF MEDICINE

Copyright 1941 by the Medical Society of the State of New York

VOLUME 41

JANUARY 15, 1941

NUMBER 2

Editorial

As a Matter of Fact

In the *New York Times* of December 17, 1940, Mrs. Roosevelt is reported to have said that the rejection of men physically not fitted for military service would "give impetus to the movement for a comprehensive and nationwide health program. *The discovery of the need is the first step toward creating a demand—the rejection of men for service dramatizes the need*"*

A nationwide health program, comprehensive, well considered and planned, devoid of political considerations, based on demonstrable need and adjusted to the ability of the people to pay for it, would unquestionably have the support of the medical profession. Speaking throughout the Nation in 1940 Dr. Nathan B. Van Etten, president of the A. M. A., has said and reiterated "In advocating a new health program, I believe that a National Department of Health with a Secretary of Health in the cabinet is as important as a War Department with a Secretary of War.

"Defense against disease is as important as defense against a military enemy."

On the need for a new health program there is general agreement, and this JOURNAL advocates it and will support such a movement to the limit of its ability and influence. Mrs. Roosevelt says

"*The discovery of the need is the first step toward creating a demand*"**

With this idea we can agree. But we must insist that such evidence as is ad-

duced in support of the need be factual. If Mrs. Roosevelt will base her discovery of the need on Dr. Van Etten's statement "Our mental unfitness is revealed by 500,000 hospital beds occupied by the institutionalized insane. Our physical unfitness by a half million active syphilitics," her discovery will be solidly based on fact.

But as to the statement "*the rejection of men for service dramatizes the need*," we can concede only that it is dramatic. For, on December 17, 1940, Colonel McDermott, director of the Selective Service in New York City, released to the press an analysis of the causes for rejections compiled by the Medical Division which gives the details of the medical causes for rejection by 120 local boards and the local induction centers. This sampling of registrants comprised 1,643 men of whom 1,213 were accepted for full military duty. There were 430 rejected as disqualified for full military duty or designated for limited duty only. For the information of our readers we publish herewith the causes for rejection of the 430 men.

Causes for Rejections	Primary	Secondary
Underweight	26	17
Overweight	11	12
Deficient height	2	1
Poor chest expansion	0	5
Defective vision	74	32
Chronic otitis media	19	4
Impaired hearing	4	9
Nasal defects	3	5
Infected tonsils	0	3
Speech defect	0	5
Insufficient teeth	88	20

* Italics ours.—Editor

Causes for Rejections	Primary	Secondary
Disease of gums	4	1
Deformity of jaw	1	0
Rheumatic heart disease	15	2
Valvular heart disease	30	7
Myocarditis	1	2
Hypertension	8	21
Tachycardia	3	12
Congenital heart disease	2	1
Hypotension	0	1
Enlarged heart	3	9
Systolic heart murmur	3	6
Angina pectoris	1	0
Hernia	16	9
Peptic ulcer	3	1
Hemorrhoids	0	10
Pilonidal sinus	1	1
Varicocele	4	6
Hydrocele	0	3
Disease of skin	1	1
Deformity of head	1	0
Deformity of spine	4	12
Loss of limb	4	0
Loss of toe or finger	1	1
Paralysis of limb	18	3
Defective joint	5	1
Deformity of limb	10	5
Varicose veins	2	7
Flat feet	1	16
Osteomyelitis	2	0
Hammer toe	0	1
Pulmonary tuberculosis	15	0
Chronic bronchitis	2	1
Bronchial asthma	1	0
Pleurisy	1	0
Spontaneous pneumothorax	1	0
Hemoptysis	0	1
Deformity of chest	0	3
Undescended testicle	2	1
Syphilis	6	90
		(Positive Wassermann)
Doubtful Wassermann	0	26
Gonorrhea	0	1
Albumin in urine	0	2

We shall draw no conclusions from this sampling, we present it merely in evidence, marked Exhibit A, for study. As a guide, let us ask

1 Does this sampling even remotely suggest any great need for a health program?

2 In the judgment of any competent physician do the rejections by cause indicate that more than a very small percentage of the defects could have been prevented by previous medical care or attention?

3 Are not the majority of the rejections due to causes beyond the help of medical care? Are they not of a kind which even the most extensive health program could not obviate?

If statistics as they become available from the rest of the Nation parallel this regional sampling, even the most expert dramatists will apparently be able to find little material for their art in the rejection of men as unsuited for military service. However, as they wait for further reports from Selective Service headquarters, may we call their attention again to the 500,000 hospital beds occupied by the institutionalized insane and the half-million people suffering from active syphilis mentioned by Dr. Van Etten? Surely here is stark tragedy enough to dramatize the need for an effective national health program without going further afield, but, if go they must, then how about the insane who are not institutionalized? Or, are there none here?

Physical Education

Medicine has a lively interest in the subject of physical education. In the State of New York, physical instruction in the public school system is a function of the State Department of Education of which a special division is responsible for its administration. Instruction is given in all the local schools to all the children of the various school districts who are not disqualified to receive it. Presumably there is a statewide program promulgated

by the Department based on a rational philosophy and founded in the need of American youth for physical instruction.

What is the program? How broad is it? What are its objectives? A goodly number of physical instructors are working daily in a vast number of schools throughout the state to help prepare a great number of children for something. For what? For an adult life to be spent largely in riding comfortably in motor

vehicles, airplanes, trains, and busses? For an adult life otherwise devoted to operating machine tools, typewriters, filing systems, dictaphones, or Diesels? For adult evenings playing bridge, going to the moving pictures, drinking at bars, or dancing on floors so crowded as to make a subway guard blush? Or perhaps for Army or Navy life?

Our system of American education in general has been and possibly still is based largely on the philosophy of success. According to Dr. E. N. Ferris "it covers the ground without cultivating anything in it." What does it contribute toward making life endurable, even enjoyable, for those who consider themselves or are considered by others as failures? Dr. Carrel and many thinking psychologists emphasize the fact that mere muscular efficiency is inadequate to living. How then is the system of physical education in our public

schools to be integrated with the other factors—mental, spiritual, and recreational? By an expansion and broadening of the program of physical education? Perhaps Dr. Ehrlanger of Columbia University might have something to contribute to a discussion of this nature.

The national emergency is forcing upon us the necessity for serious discussion of objectives. A national health program is at least in contemplation. In such a program, the physical educators of the various states will play a conspicuous part as will the physicians of the Nation. Is it not time for both these groups to define more clearly the objectives and methods by which the national interest will be more effectively served and the individual be educated by a curriculum which not only covers the ground but which also cultivates something in it?

Home Sweet Home

One by one our old-fashioned, cherished illusions fall like thin slices of bologna before the keenly cutting edge of factual research. Home and mother! To how many childish minds have these words conjured up a picture of safety, security, comfort? Yes, and to how many adult imaginations, parched by desert heat, lost in dread jungles, lonely in countless cruel, throbbing cities, or parked against some sordid, tear-splashed bar have they brought a nostalgic, sentimental comfort? Possibly even to you, gentle reader, but not to the United States Public Health Service.

"More than 23,000 deaths occur annually as a result of accidents in the house, or nearly 2 per cent of all deaths in the United States and 23 per cent of accidental deaths (all places of occurrence). Although outranked by certain major causes of death, home accidents are the cause of more deaths than diphtheria, scarlet fever, whooping cough, and measles combined, of more than appendicitis, of nearly as many deaths as diabetes, of over two-thirds as many deaths

as automobile accidents, and of over a third as many deaths as tuberculosis,

a large proportion of these home accidents occurred among children and adults in the most productive ages, many of the persons surveyed had permanent orthopedic impairments or were blind as a result, housewives themselves sustain one-third of all serious home accidents."*

Here is a problem of major seriousness, the gravity of which, it seems to us, has not been recognized by physicians. We urge our readers to study the entire report carefully, especially the tables showing the accident rate in relation to income levels. There is here a severe indictment of housing conditions with appalling conclusions to be drawn. It is inevitable that with the speed-up of industry the industrial accident toll should rise sharply. There is a means, however, of combating this rise in the established safety-first campaigns—by education and factory safety inspection. No such programs

* Accidents in the Urban Home as recorded in the National Health Survey. Pub. Health Rep. 55, No. 40, pp. 2083-2084.

exist to our knowledge by which accident-prevention in the home is being publicized Why should such a campaign not be undertaken?

Here is a fertile field for the exercise of the radio mandate by the Society

There are few homes to which the radio does not permeate It seems to us that the opportunity is open for good, dramatic presentation of this material under the sponsorship of the profession

Stilbestrol in a Sex Offender

It seems premature to comment upon the action of an estrogenic substance which is still under investigation by the Council on Pharmacy and Chemistry of the American Medical Association However, the publication of Dunn¹ in a recent issue of the *J.A.M.A.* is worthy of comment

Others have recorded the action of stilbestrol on gynecomastia, on the liver, and on several phases of the menstrual cycle Untoward symptoms have been reported, notably gastric distress, lassitude, headache, and skin eruptions

Dunn treated with stilbestrol a male sexual criminal who was sentenced to prison for repeated offenses against minor females Examination of this individual showed a high urinary secretion of testicular hormone and the gonadotropic factor This excluded the cen-

tral nervous system as the exciting cause Physical examination revealed an oversized penis and testes

Upon administration of 5 mg of stilbestrol daily until a total of 480 mg was taken over a period of ninety-six days, a sensitiveness in both nipples and a lump in each breast were evident This enlargement of the breast corresponded to the development produced in young females who had taken stilbestrol Of greater moment is the therapeutic effect which the author achieved The penis and testes were reduced in size by one third "The patient states that there is an absence of libido and that masturbation does not produce an ejaculation of seminal fluid" This alteration from a criminal hypersexual to what, for this individual, might be considered a hyposexual state by the use of stilbestrol, is a valuable contribution to forensic medicine

¹ Dunn, C W *J A M.A.* 115 2263 (Dec 28) 1940

Psychic Esophageal Spasm

The somatic responses to emotional upsets are indeed varied More and more, we are beginning to realize that psychic factors can account for a multitude of symptoms that ordinarily are attributed to organic disorders In a previous issue of the *JOURNAL*,¹ we alluded to the work of Stokes, Beerman, and Ingraham² concerning the psychoneurogenic component in the allergic states Faulkner³ has visualized bronchoscopically alternate widening and contraction of the bronchi in response to suggestion

By further study, Faulkner has shown that alterations in the functional activity and anatomic status of the esophagus can be brought about through suggestions that call for such emotional response as grief, anxiety, fear, and anger Conversely, these spastic phenomena can be relieved by inducing emotions of happiness, enthusiasm, and security

He has studied 13 cases, all of which were referred for esophagoscopy because of symptoms referable to interference in swallowing or to recurrent vomiting of blood He distinguishes five groups, none of which is clearly separable from the others In all of them, spasm could be either aggravated or relieved depending upon the type of emotion aroused All the patients experienced a sense of insecurity or impending danger, either religious, social, marital, or financial The esophageal spasm stands in direct relationship to the intensity of the psychic problem That this reflex phenomenon is due to psychic factors is shown by the fact that problems which are of no vital interest to the subject will elicit no esophageal reflex

The work of Faulkner indicates the necessity for detailed study by esophagoscopy of all cases wherein a dysfunction of this structure is evident While strictures, ulcers, malignancies, and foreign bodies are the common causes of dysphagia it must be borne in mind that psychic episodes may produce similar

clinical pictures Undoubtedly, other viscera are subject to similar emotional stimuli

Where sedatives and antispasmodics such as atropine bring no relief, medicinal therapy will

merely prolong the identification of the etiologic factor responsible for the esophageal disturbance Esophagoscopy, skillfully performed, differentiates the organic from the inorganic lesions

Correspondence

THE CONNECTICUT STATE MEDICAL JOURNAL

54 Church Street, Hartford, Connecticut

December 3, 1940

To the Editor

Your editorial, "Coals to Newcastle," hit the bull's eye all right Let me tell you how much I appreciate your complimentary remarks on our Medical Preparedness Number When I finished with the dummy and had everything put to bed that belonged in it I felt that it was rather a poor job, not nearly as good a one as I had hoped to turn out Several of our prospective writers for that number, however, did not come across for one reason and another

About the question of insurance for the doctor during wartime, or, in fact, during the present peacetime training I was really quite concerned with your comments on the subject as they seemed too misleading to allow to go Many other State Journals have picked up your editorial and copied it I hope in the January number to have the benefit of our insurance talent in this city expressed in no uncertain terms so that the matter may be clarified In all this I have only the greatest respect for you and the way you are carrying on in a position that I know is anything but easy

Just by way of a little comeback and to remind you that other printers sometimes forget their quotation marks I submit the following

C.S.M.J 4 399

We learn from the Journal of the South Carolina Medical Association that there are many small communities in that State interested in finding good doctors who will locate in their midst For the past two years the requests have been extremely urgent and only recently it was noted that the South Carolina Medical Journal carried an advertisement announcing a field open to a young physician "who had had and is inclined toward surgical experience" *This opportunity may appeal to one who dislikes the rugged New England winters South Carolina is making rapid strides in scientific medicine*

N.Y.S.J.M 40 1585

The Journal of the South Carolina Medical Association reports that there are many small communities in that State interested in finding good doctors who will locate there For the past two years the requests have been extremely urgent, and only recently the South Carolina Medical Journal carried an advertisement announcing a field open to a young physician "who had had and is inclined toward surgical experience" *This opportunity may appeal to one who dislikes the rugged northern winters South Carolina is making rapid strides in scientific medicine*

Best regards Your Journal has improved 100 per cent since the reorganization

Sincerely yours,

STANLEY B WELD, M.D., Editor

1941 ANNUAL MEETING

Attention is called to the change in dates for the 1941 Annual Meeting of the Medical Society of the State of New York It will be—and this is final—on April 28, 29, 30, and May 1, in Buffalo, at the Hotel Statler

Suggestions for Contributors to the

NEW YORK STATE JOURNAL OF MEDICINE

THE NEW YORK STATE JOURNAL OF MEDICINE asks its contributors to follow the suggestions listed below in the preparation of their articles. In this way they will greatly facilitate the expeditious publication of the JOURNAL. These suggestions have been devised in order to save correspondence, avoid return of papers for changes, minimize the work of preparation for the printer, and save the high costs of corrections made on galley proof.

Size of Articles.—It is earnestly desired that scientific articles shall not exceed ten JOURNAL pages at the outside. Even that number of pages tends to lower reader interest. An average of five or six seems to be the most desirable from this point of view. Calculation can readily be made by multiplying the number of double spaced typewritten manuscript pages by the fraction two-fifths.

Manuscripts.—Papers must be typewritten on one side only of white sheets consecutively numbered, and be double spaced with one-inch margins. They should be prepared with great care so as to be typographically correct. All headings, titles, subtitles, and subheadings should be typed flush with the left-hand margin.

Titles.—The title should be *brief* and typed in capital letters. The subtitle can be longer and should be typed in cap and lower case letters. Under the title, or subtitle, if there is one, should appear the name of the author and city in which he lives.

Subheadings.—Subheadings should be inserted by the author at appropriate intervals.

References.—It is the unflinching practice of the NEW YORK STATE JOURNAL OF MEDICINE to use specific "references" rather than "bibliography." There should appear in the text reference numbers, typed above and to the right of the word to which there is a reference. A list, consecutively numbered, should include the following items.

- a. **Books**—author's surname followed by initials, title of book, edition, location and name of publisher, year of publication, volume, and page number. Thus, Osler, W. Modern Medicine, ed 3,

Philadelphia, Lea & Febiger, 1927, vol. 5 p 57

- b. **Periodicals**—author's surname followed by initials, name of periodical, volume, page, month (day if necessary), year of publication. Thus, Leahy, Leon J. New York State J. Med. 40: 347 (Mar 1) 1940.

NOTE. The JOURNAL does not include titles of articles.

Case Reports.—Instead of abstracts of hospital histories, authors should write these reports in a narrative style with properly completed sentences. All unimportant details should be deleted with such general negative statements as fit the case.

Tables.—While tables are very useful on lantern slides in the reading of papers, they fail of this purpose to a large extent in the printed page. For that reason it is urged that they be incorporated in the text.

Illustrations.—These should be kept to the minimum necessary to make clear the points to be registered by the author. In some instances they are imperative to proper understanding, in others they are merely picturesque.

Where illustrations are to be used they should accompany manuscripts and each should always be referred to in the text, preferably by number. Drawings or graphs should not be larger than 12 × 16 inches, and must be made with jet black India ink on white paper or tracing cloth. *Do not use typewriter for lettering.* The smallest lettering on 8 × 10 inch copy should be no less than 1/4 inch high. Cross-section paper (white with black lines) may be used, but should not have more than 4 lines per inch. If finer ruled paper is used, the major division lines should be drawn in with black ink, omitting the finer divisions. In the case of finely ruled paper, only blue-lined paper can be accepted. Lettering and all markings must be large enough to be readable after reduction. Mail rolled or flat. Photographs should have clear black and white contrasts and be on glossy white paper.

Whenever possible "crop" photographs, i.e., mark portion that can be excluded when reproduced. Crop marks should be on *margin* of photographs—not on the photographs.

It is important to mark the top of the illustration on the back, also its number as referred to in the text, thus, Fig 1, 2, and the name and address of the author.

Legends should be typewritten on one sheet of paper and attached to the illustrations.

SPECIFIC TREATMENT OF PNEUMONIA

With Special Reference to Chemotherapy and Antipneumococcus Serum*

EDWARD S. ROGERS, M.D., Loudonville, DAVID D. RUTSTEIN, M.D., and
ALEXANDER D. LANGMUIR, M.D., Albany, New York

IT IS essential for the physician to be acquainted with the field of usefulness and with the limitations of two agents in the specific treatment of pneumonia and other pneumococcal infections. These are drugs of the sulfonamide group and specific antipneumococcus serums. The drugs that have been of greatest value in the treatment of such infections are sulfapyridine and sulfathiazole.

Even though the use of chemotherapy alone may be intended, it is an essential of good treatment to be prepared to give serum, if necessary, by obtaining sputum for typing and blood for culture before drug treatment is begun. If severe toxic manifestations necessitating interruption of drug therapy occur, if the patient is exhausted from nausea or vomiting, if the response to the drug is not satisfactory, or if it is impossible to secure adequate intake of the drug, the switch to serum therapy can then be made with a minimum of delay.

Chemotherapy

Indications—In the absence of definite contraindications, sulfapyridine or sulfathiazole should be given to every case of pneumonia as soon as the diagnosis has been established and specimens of sputum and blood have been obtained for submission to a laboratory for typing and culturing. Drug treatment has a particular advantage in the treatment of infections in which multiple pneumococcal types occur and in some instances in which mixed infections of pneumococci and other microorganisms are found. When pneumococci cannot be obtained on careful bacteriologic examination, a therapeutic test with either sulfapyridine or sulfathiazole for thirty-six to forty-eight hours should be attempted. If no benefit occurs, drug therapy should then be discontinued.

From the Bureau of Pneumonia Control, Division of Communicable Diseases, New York State Department of Health, Albany. The authors are particularly indebted for the suggestions and criticisms of the following authorities in pneumonia: Drs. Jesse G. M. Bullowa, Russell L. Cecil, Lloyd D. Felton, Maxwell Finland, Colin MacLeod, and Norman Plummer.

* Due to the rapid development of both serum and chemotherapy, the following discussion regarding their relative merits must be considered as somewhat tentative, and changes in point of view may be indicated as more information becomes available.

At present there is insufficient information to establish the relative superiority of sulfapyridine or sulfathiazole. While they appear to have equal therapeutic effect, they display characteristic differences which usually serve to direct their choice in a given case. Although sulfanilamide may have some effect, especially in type III pneumococcal pneumonia, dramatic response to its use such as is seen with sulfapyridine, sulfathiazole, or serum is rare. Sulfanilamide is less toxic than the other drugs and might be recommended for the treatment of pneumonia due to hemolytic streptococcus. Although the hemolytic streptococcus may cause pneumonia, it is frequently found in normal throats or in the sputum as a contaminant. Since sulfapyridine is equally effective in the treatment of infections with hemolytic streptococcus, in general it is preferable not to use sulfanilamide in the treatment of an acute pneumonic infection where there may be the slightest chance of its being caused by the pneumococcus. Pneumonias due to *Staphylococcus aureus* should be treated with sulfathiazole.

Contraindications—A history of serious toxic reaction to any of the drugs of the sulfonamide group constitutes a major contraindication to the use of sulfapyridine and sulfathiazole. Chemotherapy also may be contraindicated in patients with renal disease, especially in the presence of nitrogen retention, in patients with persistent vomiting or in whom pneumonia develops after an operation on the gastrointestinal tract where vomiting might be dangerous, or in those with hepatic disease. These contraindications must be considered in relation to the severity of the illness and the effectiveness of the alternate forms of therapy. There are very ill patients for whom serum therapy either is not available or is ineffective and in whom the dangers of a drug reaction must be risked in order to attempt to save life. Pre-existing severe anemia is not a contraindication, provided the hemoglobin is maintained at a safe level by repeated small transfusions.

Dosage—The oral dosage of both sulfapyridine and sulfathiazole is fairly well standardized—an initial dose of 2 Gm. for the average adult repeated in four hours and 1 Gm. every

four hours thereafter.* Patients receiving sulfathiazole tend to have lower blood levels of the drug than those receiving sulfapyridine, although the lower level of the former seems to be equally effective. In general, sulfathiazole tends to become acetylated less than does sulfapyridine. This would appear to be an advantage since the acetylated form of either is therapeutically inactive.

It is important to continue the administration of either drug for thirty-six to forty-eight hours following apparent recovery by crisis or lysis. Premature cessation of drug treatment may be followed by a recrudescence following excretion of the drug through the kidneys. The temptation to interrupt drug therapy as soon as the pulse and temperature approach normal levels must be avoided, as fatalities that might have been prevented occasionally occur under these circumstances. Since prolonged administration of small amounts of these chemotherapeutic agents may allow the infecting microorganism to become drug fast, termination of drug treatment should be abrupt. If a recrudescence of the infection occurs following interruption of therapy, treatment should be resumed with a large dose (4 Gm.).

Most patients benefited by chemotherapy will show rapid improvement. Neither drug should be continued for more than seventy-two hours in the absence of any response, as the danger of toxic reactions rapidly increases. If an obviously favorable response does not follow eighteen to twenty-four hours of adequate therapy with sulfapyridine or twenty-four to thirty-six hours of sulfathiazole, it is not likely to do so. Serum therapy should be started at the first indication that drug treatment alone may not succeed, especially in the presence of pneumococci of types I, II, IV, V, VII, VIII, or XIV. In drug refractory cases of other pneumococcus types, especially when such types are found on indirect (mouse) sputum examination, decision as to therapy may be difficult. Serum for the type suggested may be tried, but it is desirable also to determine the amount of free drug present in the blood of the patient. If the level is below 4 mg. per hundred cubic centimeters, the administration of the drug should be continued with larger dosage.

Concentration in the Blood.—The absorption, excretion, and degree of acetylation of these drugs are irregular and unpredictable in differ-

ent patients. It is considered desirable to have a blood concentration of the "free" drug of 4 mg. per hundred cubic centimeters or more, although many patients recover with lower levels. Nausea and vomiting may make it difficult to estimate the absorption of the drug, and variations in renal efficiency make it equally difficult to predict the excretion.

A sample of 4 milliliters of oxalated venous blood is satisfactory for the determination of both the free and total drug levels. A considerable number of diagnostic laboratories in New York State are now in a position to make such quantitative determinations. Physicians should inquire of their local laboratory director where tests of this nature can be undertaken.

Parenteral Administration.—Although oral medication is satisfactory for most patients, there are soluble derivatives of these drugs (sodium sulfapyridine and sodium sulfathiazole) which can be given parenterally. Parenteral administration should be used only (1) when the patient is so acutely ill that it would be unwise to wait the necessary few hours for the orally administered drug to attain an adequate blood concentration, (2) when there is failure of absorption of the drug after adequate oral dosage, or (3) when there is intractable vomiting. Routine use of these salts or their continued administration throughout the course of the illness is not recommended. If the intravenous dose of 4 Gm. for a 150-pound adult is supplemented by an oral dose of either of these drugs of 1 Gm. every four hours, an adequate level of the drug will be maintained in most cases.

After calculating the necessary amount of the drug depending upon the body weight of the patient, the proper amount of the dry powder is weighed out under sterile precautions and dissolved in sterile distilled water to make a 5 per cent solution. The injection may be started with a small amount of sterile normal salt solution in order to make certain that the needle is well within the vein and that no fluid is leaking out into the subcutaneous tissues. The solution of sodium sulfapyridine may then be added and allowed to run in slowly (a period of twenty minutes is advised).

The last portion of the drug solution is then washed through the intravenous set with a small amount of salt solution. No other solvent such as glucose solution or blood for transfusion should be used. Use of the latter has been associated with sudden fatality.

* An alternate method sometimes advised is the initial administration of 4 Gm. followed by 1 Gm. every four hours.

It has been reported that dilute solutions of these salts (0.5 per cent) may be given by hypodermoclysis without local reactions, and it is claimed that such administration prolongs the period during which an effective blood level may be maintained. Rectal administration also has been reported, but it is not recommended as it is impossible in the usual practice to determine the total amount of drug absorbed. *Intrathecal administration of the sodium salts of either sulfapyridine or sulfathiazole in the treatment of meningitis must not be used* as it has been followed by thromboses of the vessels in the spinal cord.

Toxic Reactions—The common toxic effects of both drugs are now fairly well recognized. Most common are nausea, which occurs in about two-thirds, and vomiting, which occurs in about one-third of the patients receiving sulfapyridine. It is usual to find that the patient feels poorly and depressed during the entire period of drug administration, even though the acute symptoms of the disease may have subsided. The nausea and vomiting following sulfathiazole therapy is less frequent and less severe, and the mental depression is not so marked. These symptoms usually are not avoided by parenteral administration. Some alleviation occasionally is afforded by administering the drug in powdered form in milk or mixed with semisolid food. In some patients it is almost impossible to continue oral therapy without extreme discomfort. In other patients, vomiting and even nausea subside while the drug is being taken regularly. These symptoms are not dangerous in themselves, but their secondary effects may be, since their occurrence often makes it psychologically difficult to continue the treatment of a patient who has apparently recovered but in whom the danger of recurrence still might be present if drug administration were to be stopped. Moreover, nausea and vomiting occasionally make it difficult to maintain an adequate fluid intake.

Hemolytic anemia of varying severity infrequently follows the use of these drugs and can be detected by careful clinical examination or hemoglobin determinations. Anemia associated with sulfapyridine or sulfathiazole administration probably is less frequent than that associated with sulfanilamide. When mild it usually can be controlled by transfusions without the interruption of drug therapy, but when severe the immediate cessation of drug therapy is indicated.

Care should be taken in interpreting the significance of a low white count. Leukopenia

without granulocytopenia is not uncommon. It may occur early and usually is transient if drug administration is interrupted. The occurrence of leukopenia without granulocytopenia prior to drug administration does not contraindicate the administration of these drugs, especially if no other therapy is available. It may even be advisable to continue drug administration, since such circumstances indicate a poor prognosis. On the other hand, a sudden leukopenia associated with granulocytopenia occurring during drug administration contraindicates further drug therapy. Such reactions rarely occur during the early period of drug administration. However, after the third or fourth day of drug treatment, daily counts of the white blood cells should be made if this serious complication is to be recognized in time. A preliminary white count and blood smear before starting drug therapy may prove essential to the interpretation of subsequent changes.

The diagnosis of drug fever often is difficult. It occurs late in the disease when other confusing conditions might exist, such as focalized infection, extension of the pulmonary process, or serum sickness if specific serum has been used. The drug may be continued with caution if the occurrence of the fever is associated with the reappearance of the extension of the pulmonary process or when there are signs of fluid in the chest, leukocytosis, or other evidence of focal complications which are, in themselves, sufficient to account for the fever. In the absence of such evidence it may be necessary to discontinue the drug in order to determine its relationship to the fever.

Drug rashes have been noted following administration of sulfapyridine and sulfathiazole. In the case of sulfapyridine these usually are morbilliform and occasionally scarlatiniform in nature. Rashes are more frequent and varied among patients receiving sulfathiazole. Especially noteworthy is the occurrence of a rash which cannot be differentiated from erythema nodosum. A careful daily examination of the patient's skin should be made. A rash without other toxic manifestations is felt to constitute a relative contraindication to further chemotherapy. It is occasionally possible to interrupt drug administration until the rash disappears and then reintroduce therapy without a recurrence of the rash. If it is necessary to continue drug administration, the patient should be watched for other toxic manifestations such as drug fever, jaundice, anemia, or granulocytopenia.

Sulfathiazole administration occasionally is

four hours thereafter * Patients receiving sulfathiazole tend to have lower blood levels of the drug than those receiving sulfapyridine, although the lower level of the former seems to be equally effective. In general, sulfathiazole tends to become acetylated less than does sulfapyridine. This would appear to be an advantage since the acetylated form of either is therapeutically inactive.

It is important to continue the administration of either drug for thirty-six to forty-eight hours following apparent recovery by crisis or lysis. Premature cessation of drug treatment may be followed by a recrudescence following excretion of the drug through the kidneys. The temptation to interrupt drug therapy as soon as the pulse and temperature approach normal levels must be avoided, as fatalities that might have been prevented occasionally occur under these circumstances. Since prolonged administration of small amounts of these chemotherapeutic agents may allow the infecting microorganism to become drug fast, termination of drug treatment should be abrupt. If a recrudescence of the infection occurs following interruption of therapy, treatment should be resumed with a large dose (4 Gm.).

Most patients benefited by chemotherapy will show rapid improvement. Neither drug should be continued for more than seventy-two hours in the absence of any response, as the danger of toxic reactions rapidly increases. If an obviously favorable response does not follow eighteen to twenty-four hours of adequate therapy with sulfapyridine or twenty-four to thirty-six hours of sulfathiazole, it is not likely to do so. Serum therapy should be started at the first indication that drug treatment alone may not succeed, especially in the presence of pneumococci of types I, II, IV, V, VII, VIII, or XIV. In drug refractory cases of other pneumococcus types, especially when such types are found on indirect (mouse) sputum examination, decision as to therapy may be difficult. Serum for the type suggested may be tried, but it is desirable also to determine the amount of free drug present in the blood of the patient. If the level is below 4 mg. per hundred cubic centimeters, the administration of the drug should be continued with larger dosage.

The last portion of the drug solution is then washed through the intravenous set with a small amount of salt solution. No other solvent such as glucose solution or blood for transfusion should be used. Use of the latter has been associated with sudden fatality.

* An alternate method sometimes advised is the initial administration of 4 Gm. followed by 1 Gm. every four hours.

seen late in the course of the disease who still are very sick, in patients with type III pneumococcal pneumonia, and in those with extensive pulmonary involvement. Past experience points to the gravity of these conditions. Therefore, until such a time as acceptable evidence may indicate a different course, it would seem desirable in their presence to combine serum and drug treatment. Furthermore, from theoretic considerations, the use of combined drug and specific treatment may shorten the period of drug administration and may decrease the amount of serum necessary to obtain an adequate therapeutic response.

Contraindications—Because of the risks of untoward immediate reactions, serum therapy should be used with hesitation in patients with a history of allergy to horse or rabbit proteins, patients who have positive sensitivity tests to the animal serum, patients with congestive cardiac failure, or patients who are moribund.

Dosage—Serum therapy is type-specific. It requires careful bacteriologic control. The dose of specific serum must be adequate and will vary with the individual case. In most instances, uncomplicated pneumonia in a person under 25 or 30 years of age, of four days' duration or less, responds with a rapid crisis to the introduction of 50,000 to 100,000 units of serum. In infants and small children, doses of 25,000 to 50,000 units often are adequate. These doses generally are sufficient for most types other than type II, which usually requires 100,000 to 250,000 units for uncomplicated adult cases. The required dosage increases with age, with delay in treatment, when the pulmonary process is extensive, in patients with bacteremia, in patients who are pregnant, or in those in whom there is reason to believe that purulent complications have begun while the pulmonary lesion is still active.

Various methods for the objective evaluation of the adequacy of serum dosage have been devised. The best of these are the Francis (specific pneumococcus carbohydrate) skin test and the slide agglutination test of blood antibody content as advocated by Bullock. While both of these tests have points of real merit, they are sufficiently complicated and their interpretation is sufficiently confused by conditions and exceptions to render them somewhat impracticable for use outside of hospital practice. Clinical judgment and experience must be employed in the successful use of these tests as well as in the control of serum dosage without them, and these attributes of the physician remain the key to successful

treatment. A drop in pulse rate associated with a drop in temperature is the best objective clinical sign of recovery.

The dosage that in total amount may appear to be adequate but the administration of which is spread out over too long a period of time may prove to be inadequate. One hundred thousand units given within a period of four hours to an ordinary case is considerably more effective than the same number of units given in 20,000-unit doses every eight to twelve hours over a period of two to three days. This is especially important in severe cases, since a dose of 200,000 units in a bacteremic patient may bring about an immediate recovery, whereas 400,000 or even 500,000 units spread over a period of two to five days may have little effect.

The occurrence of purulent complications of pneumonia or systemic complications not related to the pneumonia may interfere with successful serum therapy. Careful physical examination usually will reveal them if present.

It has been reported that recovery has followed the administration of repeated small transfusions (300 milliliters) in patients who seemingly failed to respond to large doses of specific serum in the absence of other explanations for serum failure.

Procedure in Refractory Cases—In all cases that fail to respond within eighteen to twenty-four hours to apparently adequate doses of antiserum, the following steps should be taken:

- (1) Repeat sputum examination for possible error in typing or for mixed infection. Culture sputum for presence of hemolytic streptococcus and other possible infecting microorganisms.

- (2) Ascertain result of original blood culture and take additional culture.

- (3) Make a search for localized infection or other cause of persistent symptoms.

- (4) Institute drug treatment if that has not already been done.

- (5) Continue serum administration unless changes in therapy are specifically indicated.

Immediate Serum Reactions—Immediate reactions to serum are fairly frequent but are usually amenable to control. They may be divided into four groups*: thermal or chill, anaphylactic, circulatory, and a residual group of heterogeneous character. More than one of these groups of reactions may occur in the same patient.

* The study upon which this classification of immediate serum reactions is based will be published in the *Archives of Internal Medicine*.

followed by severe conjunctivitis and scleritis which contraindicate further therapy. This toxic complication has not been noted following the administration of sulfapyridine.

Cyanosis has been considerably less frequent following sulfapyridine and sulfathiazole than after sulfanilamide, and its occurrence does not contraindicate further chemotherapy.

There have been occasional reports of apparent hepatic damage associated with sulfapyridine administration. However, interpretation is extremely difficult due to the fact that toxic hepatitis with jaundice may occur in pneumonia in the absence of either drug or serum therapy.

One of the most important complications of therapy with these drugs concerns kidney function. Hematuria has been noted with considerable frequency and often has been associated with symptoms suggesting renal colic. Nitrogen retention and edema, with or without hematuria, and even complete anuria have also been noted, and fatalities due to this complication have occurred. These conditions may appear at any time during the course of the treatment. In most instances when a renal complication is recognized early, discontinuance of the drug and the administration of large quantities of fluid and salt result in prompt improvement.

Determination of the amount of the daily excretion of urine is of great value and can be performed easily. In the home, any convenient household measure may be used. The fluid intake should be sufficient to maintain an output of at least a liter a day. Drug treatment should be stopped if, during drug therapy, a sudden drop in urine volume occurs in a patient who is receiving an adequate fluid intake.

Microscopic hematuria and crystals of the acetylated form of the drug frequently have been found in the urine of patients receiving drug treatment. This finding does not indicate cessation of drug therapy, but is a warning sign. Patients receiving these drugs should have a daily urine examination, and whenever possible a microscopic examination of the sediment should be performed.

Symptoms of nitrogen retention, such as drowsiness or coma, indicate the need for a determination of the nonprotein or blood urea nitrogen and cessation of drug treatment if nitrogen retention is demonstrated. Throughout drug administration the fluid intake must be maintained, by parenteral routes if necessary, in order to avoid renal irritation or obstruction from the concentrated drug.

Patients receiving the sodium salts of these drugs are equally subject to the same toxic manifestations.

It should be re-emphasized that relapses may occur with premature discontinuation of these drugs following evidence of recovery on the part of the patient. Hence, these drugs should be continued until such a time as natural immunity develops. Since this time varies so widely in different patients, no categorical statement can be made as to the optimum time for stopping treatment. On the other hand, the longer treatment is continued, the more opportunities there are for serious toxic effects to occur. Where immunity is given artificially by means of specific antipneumococcus serums, the danger of relapses, at least with the same microorganisms, is probably lessened.

Meningitis.—In pneumococcus meningitis, adequate doses of sodium sulfapyridine should be given intravenously to obtain and maintain a blood level of free drug of at least 10 mg per hundred cubic centimeters. Oral administration alone may not be sufficient. Sulfathiazole should not be used in pneumococcus meningitis, since the level of this drug in the spinal fluid at a given level of the free drug in the blood is much lower than that obtainable with sulfapyridine.

Serum Therapy

Indications.—Specific antipneumococcus serums have proved effective in reducing the death rate and bringing about rapid clinical cures in cases of pneumonia due to pneumococci of many types,* particularly types I, II, V, VII, and VIII in adults and type XIV in infants and children. Some caution should be observed in interpreting the significance in the sputum of types other than these. Pneumococci identified by the direct (Neufeld) method of sputum typing are considerably more likely to be the etiologic agent than are microorganisms that can be found only by indirect methods such as mouse inoculation. However, at least two satisfactory specimens of sputum should be examined before the attempt to obtain a positive result on direct examination is abandoned.

Combined specific serum and chemotherapy may prove lifesaving in patients with bacteremia, in pregnant women, in patients over 50 years of age who are severely ill, in patients

* At the present time type-specific antipneumococcus serums are supplied by the New York State Department of Health for the treatment of nearly all the recognized types of pneumococcus pneumonia.

profuse cold perspiration, constrictive chest pain, drop in blood pressure, or sudden death. Circulatory reactions occur primarily in older individuals or those with a history of pre-existing cardiovascular disease, may simulate medical shock and occasionally are fatal. They are correlated neither with a positive history of allergy nor positive protein sensitivity tests. Caution should be observed in the administration of serum to persons over 50 years of age or those with pre-existing cardiovascular disease. Epinephrine seems to be of some value in the treatment of circulatory reactions. Further serum therapy is contraindicated, and reliance may then have to be placed upon chemotherapy alone. If, however, it becomes imperative to give the patient more serum, a different lot of antiserum should be used.

There remains a miscellaneous group of reactions including those minor symptoms that at present cannot be assigned on a logical basis to one of the first three groups. These symptoms include pain in the back, lumbar region or extremities, muscular rigidity, nausea, vomiting, abdominal pain, desire to defecate, headache, coma, dizziness, faintness, throbbing of the head, blurred vision, flushing, sensation of heat, profuse perspiration, dyspnea, cyanosis, choking, or change in the rate or rhythm of respirations exclusive of asthmatic breathing. Reactions of this nondescript group are not of serious import in themselves but are very disturbing to the patient. Epinephrine may give relief to some of these symptoms. Usually they are transient in nature and clear spontaneously, but they rarely are prodromes of more serious reactions.

The dilution of serum with salt solution does not decrease the incidence of immediate reactions of any of the above groups. From the practical point of view it is often easier to inject viscous serum if it is diluted with a small amount of sterile physiologic salt solution. However, intravenous injections of very large volumes of salt solution may prove dangerous, especially in patients with cardiovascular disease. When the injection of even a small quantity of intravenous fluid may be dangerous (e.g., acute coronary thrombosis), intra-

muscular injection of concentrated serum may be the method of choice.

Serum Sickness—Serum sickness (serum disease) occurs in about one-third of all patients treated with serum. The time of onset is variable, but it usually begins about one week after serum is given. In extreme instances it may occur on the day of treatment or over two weeks after therapy. The disease may consist of fever, urticaria, lymphadenopathy, and arthritis, singly or in combination. All of these are self-limited and usually disappear in from a few days to a week. Neuritis and carditis are rare but are serious when they do occur. Therapy consists of reassurance and analgesics such as acetylsalicylic acid and codeine. For arthritis, oil-of-wintergreen wrappings and a heated cradle over the affected parts may also help. Severe and intractable urticaria may cause the patient extreme discomfort. Treatment of this condition is purely symptomatic and generally not very satisfactory. Epinephrine gives only transient relief and so often seems to be followed by more intense itching that many patients soon refuse it. The patient should remain at complete rest in bed during the course of serum sickness.

With modern refined serums, serum sickness is not only much less frequent than formerly, but the majority of cases are mild and of four days or less in duration.

Other Methods of Therapy

Hydroxyethylapocuprene administration has been reported to be of value in the treatment of pneumococcal pneumonia. Its superiority over sulfapyridine, sulfathiazole, or specific antiserum, however, has not yet been demonstrated.

Claims have been made for the effectiveness of many other agents in the treatment of pneumonia. These include diathermy, deep x-ray, deuteroproteose, artificial pneumothorax, vaccines, and quinine. No carefully controlled studies of the effectiveness of these agents have as yet been presented. They should not be used in the treatment of pneumococcal pneumonia to the exclusion of agents of established value.

NECESSARY PRELIMINARY

Admirer Friend I see that you are now practicing medicine.

Frank Fledgling No sir, I appear to be practicing medicine, but I am really practicing economy—*Case and Comment*

BANISH THE THOUGHT

Customer "How about it—any vitamins in this food?"

Waitress "I hardly think so, sir. You see we have a man come every night who sprinkles powder around and kills them"—*The Doctor and Od Quarterly*

The thermal or chill reaction is characterized by chilly sensations or a shaking chill followed by a temperature rise. The term also includes sudden elevations of temperature without recognizable chill occurring during or shortly after serum administration. This reaction apparently is not associated with protein hypersensitivity but is related to certain substances in the serum which are capable of causing reactions in susceptible persons. Cyanosis and dyspnea frequently accompany the chill, and the sharp rise in temperature is transient and usually returns to the previous level within one or two hours after the onset of the reaction. Some patients have recurrent chills following a single dose or each of several doses of serum. Treatment is symptomatic, consisting of external heat and blankets during the chill and cooling drinks and alcohol sponges during the hyperthermic phase. Rarely are heroic measures, such as ice water enemas and an electric fan turned on the patient who is sponged frequently with alcohol and wrapped in a warm wet sheet, necessary to prevent the temperature from reaching dangerous levels. Epinephrine is of no value and may even be contraindicated in the treatment of thermal reactions. It is important not to give another dose of serum following a chill reaction until the temperature has returned approximately to its previous level, because repeated thermal reactions superimposed on a high basic temperature might prove fatal. A chill reaction does not contraindicate further serum therapy, but it is advisable to change to a different lot of serum.

Anaphylactic reactions are characterized by itching, urticaria, asthma, angioneurotic edema or laryngeal edema, occurring singly or in combination. Circulatory changes usually accompany severe reactions of this type.

True fatal anaphylactic shock following serum administration in man is rare when proper precautions have been observed. It has occurred most commonly following the administration of horse or rabbit serum to patients who are known to be sensitive or who give a history suggesting specific sensitivity to horse or rabbit proteins (hair, fur, dander, hide, or serum). Such sensitivity may have been of spontaneous origin or artificially derived as a result of previous and recent serum treatment. The former generally is the more serious and the latter of importance for a variable period of time from five days to six months usually, although induced sensitivity may persist for longer periods.

Probably the most important precautionary

measure is the carefully taken history for specific (horse or rabbit) sensitivity as indicated by asthma, hay fever, urticaria, or edema. A positive history of such manifestations following exposure to horse or rabbit protein contraindicates any attempt to treat and often even to test with the serum in question. A history of previous recent serum treatment indicates extreme caution. A history of sensitivity of specific origin other than the animal in question, such as ragweed hay fever, house dust asthma, or strawberry urticaria, does not constitute an absolute contraindication but does indicate caution in skin testing and treatment.

Skin tests to normal animal serums (such as horse or rabbit) which consist only of erythema probably have little significance, although caution in the early stages of serum administration certainly is advisable in such cases. If, however, the test shows wheal formation with blanching or pseudopodia and erythema, dangerous sensitivity may be present. A positive eye (ophthalmic) test (reddening, itching, and tearing) usually is interpreted as indicating a high degree of sensitivity. In the case of a positive eye or a strongly positive skin test, the patient should be treated with chemotherapeutic agents. If serum treatment also is needed, antiserum obtained from a different animal may be tried. If no serum of different origin is available and serum therapy is imperative, cautious and gradual administration may have to be undertaken. Minute doses of highly diluted serum should be given at first intradermally and then subcutaneously, intramuscularly, and finally intravenously. During this slow method of administration, sometimes referred to as "desensitization," the rate of increase in dosage is judged entirely by the patient's local or general reaction—the latter should not be permitted to occur if possible. Epinephrine (1:1,000)* should always be kept ready for instant use. Some authorities advise preceding treatment by the subcutaneous injection of 0.25 to 0.5 milliliter of epinephrine (1:1,000) about five to ten minutes before starting the administration of the serum and recommend epinephrine at intervals during treatment.

Sudden circulatory changes may occur in certain patients showing no evidence of the specific symptoms of anaphylaxis. These changes may produce a rapid thready or irregular pulse, asystole, "shock," "vascular collapse" sometimes associated with coma,

* Active solutions are water-clear—discoloration indicates oxidation and loss of activity.

TABLE 1—RESULT OF TREATMENT WITH OZONIDE OF OLIVE OIL

	Total No	Irritation	Dis- charge	Foul Odor	Pelvic Pain	Elimi- nation	Re- duction
Chronic cervicitis	20	9 10	9	1	1	1	9 10
Recurrent <i>Trichomonas</i> <i>vaginalis</i> vaginitis	18	15	15		1	3 1 1	1 12 14
Eroded cervix*	18	2	18			1	1 18
Atrophic vaginitis	5	5				2	5
Cervicitis with fibroid uterus	4		4				4
Cervicitis postabortal	2	2					2
Cervicitis with mild prolapse	2	2	2				2
<i>Trichomonas vaginalis</i> vaginitis in pregnancy	3	3					3
Postgonorrhea dis- charge infant	1	1	1			1	

* Sterility Three one pregnant during treatment

Locke's solution (NaCl 0.6 per cent, KCl 0.01 per cent, NaHCO₃ 0.01 per cent, CaCl₂ 0.01 per cent, and Löffler's blood serum 0.4 per cent) as used by Rakoff [Am J Obst & Gynec 37:265-72 (1939)], both with and without the addition of 10 per cent sterile ascitic fluid, were tried. It was not determined whether the failure to obtain good growth was caused by the mediums used or the isolations. The results of the test were as follows:

Time in Minutes	Motility of <i>Trichomonas Vaginalis</i> Test sample + suspension	Suspension
0	++++	++++
1	++	++++
2	0	++++
15	0	++++

Motility was graded by the limits zero to 4 plus. The above readings are the averages of three tests. A warm stage on the microscope was held at 37°C for all the tests. From the above data it can be seen that the test sample kills *Trichomonas vaginalis* in two minutes.

Clinical Material

In our series of 150 cases are included the common types of leukorrheas seen in office and clinic practice. In no case has the ozonide failed to give the patient some degree of relief of symptoms, and in many cases the results have been striking.

In our most cooperative group we had 19 cases of chronic cervicitis, 9 of which followed supravaginal hysterectomy. Nine of these complained of irritation as well as discharge. This irritation was eliminated or markedly reduced in all, the discharge being reduced in amount and quality as well.

Of 18 recurrent *Trichomonas* cases, the irritation was entirely eliminated in 3 of long-standing obstinate type, the discharge was reduced in 14, and pelvic pain was relieved in 1.

Of 5 cases of atrophic vaginitis, irritation

was reduced in all and completely eliminated in 2.

Of 18 eroded cervix cases, the discharge was reduced in quantity and quality in all, and 1 who complained of sterility became pregnant while under treatment.

In a group of 8 cases of cervicitis, 3 of which were classed as postabortal, 1 who had a highly odorous discharge was relieved of odor, and discharge was reduced in all.

In 4 cases with fibroid uterus and in 2 associated with mild prolapse, the discharge was reduced, and in 1 of the latter an annoying feeling of weight was relieved (see Table 1).

Several cases are particularly worth noting.

1 Old infantile gonorrhea. Spreads negative for gonococcus for eighteen months, persistent, irritating, odorous discharge. After one week of daily installation of 1 cc of the liquid ozonide of olive oil with a medicine dropper, the discharge and irritation had entirely disappeared.

2 A fastidious patient with recurrent neibothian cysts. The discharge following cauterization of these cysts greatly annoyed her. Treatment after last cauterization with a tampon moistened with this material, followed by daily suppositories, relieved her annoyance.

3 An itching, annoying discharge with a mild recurrent cervicitis apparently dependent upon relaxed, parous vaginal walls in a patient refusing vaginal repair was relieved to such an extent by tamponade, as above, on two occasions that the patient returns for treatment only at monthly intervals instead of once or twice a week.

4 A patient too much embarrassed by office examination to report for treatment for over a year, a long-standing case of *Trichomonas vaginalis* vaginitis, suddenly decided to get married. She came to the office for a contraceptive diaphragm. Its insertion, though done with the greatest care, caused such extreme discomfort, because of the irritated condition of the vaginal walls and the consequent narrowing of the canal, that intercourse was obviously impossible.

THE TREATMENT OF LEUKORRHEA WITH OZONIDE OF OLIVE OIL

DAVID NYE BARROWS, M D , F A C S , New York City

OZONIDE of olive oil in olive oil,* which furnishes a highly available amount of oxygen in chemical combination with a bland oil, has been used by us to treat over 150 unselected cases of leukorrhea. We have found it very effective as a remedy and also have found that it measures up to Savitz, Golerb, and Shelanski's¹ criteria for a vaginal cleanser, i.e., it is nontoxic, nonirritating, and not objectionable because of corrosiveness, toxicity, irritating properties, or general ineffectiveness.

Literature

We follow Plass² (Iowa City) in the belief that the discovery of a single etiologic factor in a case of leukorrhea does not necessarily remove the possibility of other pathogenic agents, but we have tried to classify our cases according to the outstanding factor present. He feels that chronic cervicitis is the most common cause of this complaint, but under this heading he includes erosions, eversion, and cervical polyps.

Moench³ found only 13 per cent in his series to be positive for *Trichomonas vaginalis*. Our series has shown over 20 per cent vaginal infestation by *Monilia*, especially *albicans*, has not been found causative in our group of patients during this investigation to date.

Reed,⁴ quoting from Sutton,⁵ emphasizes the probability of deep penetration by vegetable oils into the skin and feels that by its capillary network the cervix and vaginal wall should exceed the skin surface in permeability. This may account for the superior oxygenating action of the ozonide of olive oil as compared to permanganate and perborate douches.

Bactericidal and Nonirritating Properties of an Ozonide of Olive Oil

We have found this preparation to be neither corrosive, toxic, nor cosmetically unsatisfactory because of the staining of skin or utensils, and it is effective in relieving the

* The preparation employed is manufactured by the Latimer Laboratory, New York City. It is made to contain approximately 1 per cent available oxygen by weight. It is marketed under the trade name of STA-O-GEN the suppositories are called STA-O-GEN Vag-I-Caps. We are indebted to the manufacturers for the material used in these tests and for incidental laboratory tests.

patient's symptoms. Stevens⁶ calls it a "nontoxic, soothing, bland germicide." Patients sensitive to arsenic, picric acid, etc., frequently develop disappointing reactions to these drugs. The ozonide has given no irritation in over 200 cases treated under our immediate supervision. Its use in a suppository has proved valuable and allows for home treatment without the bother of frequent douching.

Laboratory Tests on *Monilia Albicans* and *Trichomonas Vaginalis*

Laboratory tests of the action of the preparation on *Monilia albicans* and *Trichomonas vaginalis* in vitro have shown the following:

Killing Time Test* (*Monilia Albicans*)—A 5-cc portion of the test sample was placed in a test tube and held in the incubator until the contents were warmed to 37 C, 0.5 cc of a *Monilia albicans* suspension (ninety-six-hour agar slant in saline) was then added to the test sample and thoroughly mixed. The mixture was held at 37 C, and at the designated intervals a loopful was removed and inoculated into sterile tubes of nutrient broth.

GROWTH

Exposure in Minutes to Test Sample						
1	2	3	5	10	15	20
+	—	—	—	—	—	—

From the above data it can be seen that the test sample kills *Monilia albicans* in two minutes but not in one minute.

Killing Time Test* (*Trichomonas Vaginalis*)—To determine the killing time of the test sample against *Trichomonas vaginalis*, the following modified spermatocidal test was carried out. Fresh vaginal swabs were taken of women suspected of harboring the flagellates. These swabs were then shaken up with a small quantity (2 cc) of a modified Locke's solution (see below) to obtain a good suspension. A drop of this suspension was then examined microscopically to determine the presence and viability of the organisms. When a suitable suspension was obtained, 1 drop of the suspension was mixed intimately with 1 drop of the test sample, and the time for complete cessation of motility determined. A drop of the suspension above was used as a control.

The above technic was resorted to because of the difficulty experienced in obtaining and culturing the flagellates. Various isolation sources and several types of mediums used failed to yield successful results. Löffler's blood serum slants immersed in Locke's solution and a modified

* Harvey A. Seil, Ph.D., of Seil, Putt and Rusby, Inc.

proportionate to the quantity and quality of the discharge at the beginning of treatment

The prophylactic use of daily suppositories during and for one week after several subsequent menstrual periods has decreased recurrences in our cases

We feel that much of the relief from the symptoms caused by a thick, often profuse, leukorrhea is dependent upon the decrease of other organisms commonly found in vaginal and cervical secretions. The review of a series of spreads (Gram's stain) taken before treatment and after a week or two of treatment lead Dr Sumner Price to the conclusion that the viscosity of the discharge and the pus cells were reduced in most instances—thinned discharge gave less adherent material on second slide (Fig 1). His chart showed that no particular groups of organisms were proved to be most susceptible to the medication, but no attempt was made to identify the specific organisms

Our usual treatment routine is as follows. The vagina is cleansed gently with a cotton swab. If not completely successful, green soap, caroid powder, etc., are used to remove adherent mucus, particularly from the cervix. Erosions, ectropion, neibothian cysts, etc., are cauterized chemically or with the actual cautery. The vaginal walls and cervix are painted gently with the ozonide.

A soft wool tampon, all or part of it saturated in the preparation, is then inserted deep in the vagina. The patient is instructed to remove this after forty-eight hours or as soon as it causes discomfort. A bland or plain water douche may be taken after removal. One suppository is then to be inserted as deeply as possible on retiring each night, using a small plug of cotton inside the introitus to prevent leakage of the oil. This avoids possible soiling of the bedding or night garments. A douche, as above, may be taken before inserting each new suppository. Often the suppositories can be used every second night to give the oil more time to act on the vaginal areas. If the patient complains that

the suppository is slow to dissolve, we advise her to puncture the suppository with a pin before insertion.

The office treatment is repeated at bi-weekly or weekly intervals as the occasion demands.

In cases where the vaginitis is so severe that tamponade is undesirable, the ozonide is applied gently in the office at daily or less frequent intervals, and the suppositories are employed as early as practicable, and are followed by tamponade later—as soon as it will not cause mechanical irritation.

If chemical cauterization of the cervical or vaginal lesions is indicated, these measures can be carried out before the application of the ozonide, bearing in mind its lack of chemical incompatibilities, since it provides nascent oxygen from a bland vegetable oil vehicle.

Conclusions

(1) Ozonide of olive oil in olive oil is effective in the treatment of leukorrhea in general. (a) it eliminates unpleasant odor of discharge, (b) it cuts down or eliminates the irritation inside and about the vagina, and (c) it reduces the quantity and density of the discharge, including that following cauterization.

(2) It is nonirritating and nontoxic in contradiction to the arsenic and picrate preparations, equally effective and actually soothing, especially (a) in the infantile vagina, (b) in the senile vagina, and (c) in *Trichomonas vaginalis* vaginitis of pregnancy.

These are the conclusions based on the treatment of over 150 patients.

130 East 56th Street

Lectures in obstetrics for practitioners are being held at The New York Academy of Medicine on Wednesday afternoons at 4.30.

On January 8, 1941, the lecture was on "The Immediate Treatment of Obstetric Hemorrhage," by Dr. Charles A. Gordon, director of obstetrics and gynecology, Long Island College of Medicine.

The lectures will be given as follows: January 15, 1941, "Urinary Tract Complications in Pregnancy, Labor and the Puerperium," by Dr. Arthur J. Murphy, associate attending surgeon

and assistant urologist, Woman's Hospital, January 22, 1941, "Diabetes in Pregnancy," by Dr. Herman Mosenthal, clinical professor of medicine, New York Post-Graduate Medical School, Columbia University, January 29, 1941, "Asphyxia in the Newborn," by Dr. Nicholson J. Eastman, obstetrician-in-chief, The Johns Hopkins Hospital, and February 5, 1941, "Metabolism in Pregnancy, Including Vitamin Deficiency," by Dr. Philip F. Williams, assistant professor of obstetrics, University of Pennsylvania School of Medicine.

Fig 1 All the slides were prepared by the identical technic. The discharge in the second slide is much less viscous and less adherent to the slide. The top slide, left column, has directly under it the slide taken after treatment, likewise, the third slide was taken before treatment and the fourth, after. The right column follows the same arrangement.

as was tamponade. The walls were painted lightly with the medication, and nightly suppositories were prescribed. One week later the patient reported intercourse without discomfort, and at the end of the second week, the thick, creamy discharge had disappeared and a nearly clear mucus of limited amount was all that remained.

5 A profuse, thick, greenish discharge of a recurrent *Trichomonas* was cleared to the patient's entire satisfaction by nightly suppositories for two weeks, with only two douches during that period and after one office treatment at the start.

6 An unfortunate patient of cleanly habits who, in spite of a daily douche, had such a strong and disagreeable odor from the vulva that pelvic examination was extremely unpleasant both for the doctor and his nurse-assistant standing at the

patient's side. Two tampons three days apart, saturated in the ozonide cleared up the odor so that both doctor and nurse remarked on the change.

7 Three cases of severe *Trichomonas vaginitis* in pregnancy have responded very satisfactorily.

Methods and Results of Treatment

The gross change in the character and quantity of a profuse opaque, milky leukorrhea after one or two weeks of treatment to nearly clear mucus has proved to be practically a routine result. The decrease in the amount of vulvar itching, irritation, and soiling of the clothing has been remarked by all of our patients, the degree of relief apparently being

that none of the sputums typed out after therapy²³

Effects on White Blood Count

Great stress has been laid upon the effects of sulfapyridine on the white blood count, so that particular attention was paid to this point. Counts were done on admission and daily during the time that sulfapyridine was administered. Of the children all but 2 revealed a change in leukocyte status. One dropped from 23,700 with 83 per cent polymorphonuclears to 6,600 with 50 per cent polymorphonuclears, whereupon the drug was discontinued. The other showed a rise from 10,000 with 54 per cent polymorphonuclears to 18,550 with 36 per cent polymorphonuclears. It is interesting to note that although the total white count was elevated the number of granulocytes was diminished.

In the adult group all but 6 showed no change in count. Of these, 4 almost doubled their count with the number of granulocytes remaining constant (88 to 91 per cent). Of the remaining 2, 1 dropped from 28,000 with 94 per cent polymorphonuclears to 4,950 with 58 per cent polymorphonuclears but rose again after the drug was discontinued to 6,000 with 76 per cent polymorphonuclears. The other dropped from 20,000 with 95 per cent polymorphonuclears to 1,600 with no polymorphonuclears being found on the smear. This occurred several days after the drug was discontinued. This patient had a streptococcus hemolyticus pneumonia, developed empyema, and was transferred to the surgical service for thoracotomy. He had received 84 Gm of the drug. He was treated for agranulocytosis and responded favorably to the use of pent-nucleotide. Whether this agranulocytic state would have occurred in the absence of sulfapyridine is a moot question in view of the fact that Evans and Gaisford¹ reported just such an occurrence in one of their control cases.

Effect on Temperature

Although the total duration of temperature from the time of onset of the disease to the time at which it became normal is much shorter than that resulting from treatment with sulfanilamide or other nonspecific drugs, this cannot be judged accurately at this time insofar as treatment was withheld in most cases until a sputum typing could be obtained. However, the efficacy of the drug may be judged by the duration of temperature after the institution of sulfapyridine.

In the children the average duration of tem-

perature after treatment was started was twenty-four and four-tenths hours and ranged from sixteen to fifty-two hours. This is exclusive of 1 case who was extremely toxic, ran a low-grade temperature at all times, and finally expired, another had a postoperative hemothorax whose temperature came down after sixty-eight hours, and 2 cases had fluid on admission and showed no change in their irregular temperature after treatment. Both went on to empyema and were subsequently transferred to the surgical service where closed thoracotomies were done with recovery. *Staphylococcus aureus* was recovered from the first and *Pneumococcus* type III from the second.

In the adult group the average duration of temperature after institution of therapy was nineteen and seven-tenths hours. This is exclusive of 3 cases who had delayed resolution, 2 cases who expired, 1 case complicated by a lacerated bladder, fractured pelvis, and postoperative cystotomy, 1 case of pneumonia that went on to meningitis and expired, and the case of streptococcus pneumonia who developed empyema and agranulocytosis.

Total Drug Used

As stated earlier in this paper, the dose employed was uniform in all cases in an effort to determine the total dose required and to note the differences obtained, if any, in the concentration of free sulfapyridine in the blood of patients treated with the drug. In the children an average of 6.79 Gm was given. In the adult group an average of 30.1 Gm per case was given. This figure includes those cases complicated by empyema, delayed resolution, meningitis, and reinstitution of therapy following a secondary rise in temperature. If these are excluded, the average total dose per uncomplicated case becomes 20.95 Gm. Both these figures closely approximate the total dose of 25 Gm recommended by the British investigators.

Blood Concentration

It was surprising indeed to observe the wide variation in blood concentration of free sulfapyridine. It was noted also that the rapidity of fall of temperature and the degree of clinical improvement bore no relation to the concentration of free sulfapyridine in the blood. In the pediatric group the levels varied from 2 to 9.3 mg per hundred cubic centimeters. These ranges are computed from the average levels in each case. Actually, the individual determinations in each case and from case to

THE TREATMENT OF PNEUMONIA WITH SULFAPYRIDINE

MORRIS FOGEL, M D , Brooklyn

THE medical profession is familiar with the experimental work and recent reports concerning the toxicity of sulfapyridine and its efficacy in the treatment of pneumonia and other coccic infections. Therefore, a review of the literature would be superfluous at this time and we have limited ourselves to a presentation of the results following the use of the drug at the Coney Island Hospital.

Plan of Study

We present 44 cases of pneumonia treated from January to March, 1939. These were taken from the medical, pediatric, surgical, and urologic services (male and female). They were selected as to day of onset, degree of toxicity, febrile reaction, and type of infecting organism. Sulfapyridine* was administered to those who were admitted in the third or fourth day of their illness or earlier, with the few exceptions where the febrile reaction was severe and the involvement was massive. Wherever possible, treatment was withheld until the clinical diagnosis was confirmed by x-ray and the sputum had been typed. In the early cases treated, blood levels for free sulfapyridine were not determined, since standards had not as yet been prepared by our laboratory. The later cases, however, had daily determinations by the Marshall method for the determination of sulfanilamide with the substitution of sulfapyridine in the standard. White and differential blood counts were done on admission and daily during the course of therapy. The clinical course of the patients was checked by frequent physical and x-ray examinations. Repeat sputum examinations were done on a number of cases to check up on reports that type specificity of the infecting organism was lost. The dose of the drug used was that suggested by Bullowa, which is somewhat higher than that used by the various British investigators.¹ In adults 4 Gm. was given as an initial dose, followed by 1 Gm. every four hours during the day and night. In children it was given on the basis of weight up to 25 pounds, 2 Gm., up to 40 pounds, 3 Gm., and 50 pounds or over, 4 Gm. as an initial dose to be followed by 1 Gm. per 10

pounds body weight divided into six equal doses and given within twenty-four hours. In no case was more than 1 Gm. given every four hours. The drug was continued until the temperature was 100 F. or below for forty-eight hours. It was given crushed and suspended in milk or water and was repeated if vomiting occurred in less than one-half hour. In 1 case because of severe vomiting it was given by rectum suspended in mineral oil.

Age Groups and Involvement

Of the 44 cases of lobar pneumonia treated, 20 were children whose ages ranged from 3½ months to 8 years. There were 11 boys and 9 girls, with an average age of 2.97 and 2.03 years, respectively. The average number of lobes involved was 1.35 with 1 to 2 lobes per case. Two cases had fluid on admission.

In the adult group there were 18 men and 16 women whose ages ranged from 13 to 65 years with an average of 33 and 40.5 years, respectively. The average number of lobes involved was 1.77 with 1 to 4 lobes per case.

Sputum Types

The types encountered in the children were as follows: I, 3; III, 3; VI, 2; VII, 2; VIII, 1; XIV, 2; XXIII, 1; and 6 did not type out.

Repeat sputum examinations and gastric extractions were not done, but *Pneumococcus* type III were recovered from the chest contents of one of the cases that had had fluid on admission and went on to empyema.

In the adult group the following types were obtained: I, 4; III, 12; VII, 2; XIV, 1; XVI, 1; XVIII, 1; mixed, 2 (IV, V, and VI) (VII and VIII), and *Streptococcus hemolyticus*, 1.

Repeat sputum typings were obtained in 3 cases of type III pneumonia and in 1 case of mixed infection. One of the type III cases developed a type III pneumococcal meningitis after he had been on sulfapyridine for eighteen days. Type III organisms were cultured repeatedly from a case of pneumococcal meningitis secondary to an acute mastoid infection. In the other cases, although pneumococci were seen, they did not type out after sulfapyridine had been given. The finding of even a few cases in which sputum typings were obtained after the drug was given is in contrast to the work of the British investigators who found

Resident in medicine, associated with Dr. Philip I. Nash, director of medicine, Coney Island Hospital.

* The sulfapyridine used in this work was supplied through the courtesy of Merck & Company under the trade name of "Dagenan."

The group included 20 children and 24 adults

In a number of cases the sputum could be retyped after treatment

The types treated were I, III, VI, VIII, XIV, XVI, XVIII, XXIII, mixed (IV, V, and VI) (VII and VIII), a group that did not type out, and 1 case of streptococcus hemolyticus pneumonia

The majority of cases showed no change in the total white count. Elevation as well as fall in counts were noted

The average duration of temperature after treatment was started was twenty-five and four-tenths hours in the children and nineteen and seven-tenths hours in the adults

The average total dose of the drug given in uncomplicated cases was 20.95 Gm., 30.1 Gm., if the case was complicated, were included

Blood concentrations varied widely and bore no relation to the rate of recovery

Complications noted were delayed resolu-

tion, spread of infection, secondary rises in temperature, empyema, and meningitis

There were 4 deaths, 1 in the pediatric group and 3 in the adult group

The toxic reactions encountered were nausea, vomiting, weakness, mental confusion, hematuria, and skin manifestations

Four cases of pneumococcal meningitis were treated with 1 recovery. The results in our cases of pneumococcal meningitis do not seem to compare favorably with those obtained in England.^{4,5}

case varied from 0.5 to 11 mg per hundred cubic centimeters. It was found that the blood was cleared of the drug forty-eight hours after it was discontinued.

Spinal fluid determinations were done in 2 cases. The average concentration was found to be 41 per cent of the blood level in 1 and 76 per cent in the other.

Complications

In the pediatric group 2 were admitted with evidence of fluid, did not respond to treatment, and went on to empyema, another had a sharp drop in white blood count and a secondary rise in temperature after the drug was discontinued. The temperature dropped to normal in four hours spontaneously.

In the adult group 1 developed empyema and agranulocytosis, 1 developed pneumococcal meningitis, 3 had delayed resolution, and 3 had secondary rises in temperature.

Of those adults who had secondary rises in temperature, 1 had had a normal temperature for only twenty-four hours when the medication was stopped. Twenty-four hours later his temperature rose to its original height of 105 F, and it was found that the area of consolidation had increased in size. The concentration of sulfapyridine in his blood was zero at this time. His response to a second course of treatment was as rapid as originally (sixteen hours), and he made an uneventful recovery. Another developed a small amount of interlobar fluid which absorbed spontaneously. The third had a rise in temperature with neither spread nor fluid. She responded to further administration of the drug.

Deaths

There was 1 death in the pediatric group. This was an infant, aged 2 months, who was cachectic on admission and ran a continuous low-grade temperature ranging from 99 to 101 F and up to 102 F on four occasions. A typing could not be obtained, although sputum, throat smear, and gastric contents were examined.

In the adult group there were 3 deaths. All were type III pneumonias. Of these, 1 had been chronically ill for the past nine years and was admitted to the surgical service with an acute abdomen. He was also suffering from arteriosclerotic heart disease and avitaminosis B. His blood culture was positive for type III pneumococci. He expired twenty-four hours after treatment had been started. The third died of type III pneumococcal meningitis, his pneumonia had cleared as shown by x-ray.

Acute pneumococcal meningitis had developed during the treatment of the pneumonia with sulfapyridine.

Toxic Reactions

In most cases there was nausea. Six of the pediatric cases had frank vomiting and 1 had a transient hematuria. In the adult group only 5 had no reaction following the use of the drug. The remainder had gastric upsets varying from mild nausea to such extreme vomiting that the drug was given in 1 case per rectum suspended in mineral oil. Cyanosis, weakness, and mental confusion were seen in several cases. One had frank hematuria. Four cases, 3 of which survived, became completely irrational for several days. Two cases of skin rashes developed. 1 had a form of diffuse erythema, pruritic in nature and resembling giant wheals and the other had a morbilliform rash. The latter cleared as soon as the drug was discontinued.

Other Cases

In addition to the 1 case of type III pneumococcal meningitis complicating pneumonia, 2 other cases of pneumococcal meningitis were treated. The first was a boy, aged 5, admitted with the diagnosis of meningitis and in whose spinal fluid type XIX organisms were found. He expired twelve hours after institution of therapy. Since he was seen late in his illness and had had only 6.5 Gm of the drug, it was felt that the treatment could not be evaluated. The second was a white man, aged 30, who developed type III pneumococcal meningitis three weeks following an episode of acute mastoiditis from which type III organisms were recovered at operation. Type III organisms were cultured repeatedly from his spinal fluid. He received a total of 133 Gm of sulfapyridine and developed the diffuse rash mentioned above. He expired twenty-five days after the onset of meningitis.

One case of pneumococcal meningitis following concussion of the brain was treated successfully with sulfapyridine. Organisms were seen but did not type out.

One case of subacute bacterial endocarditis was treated with no improvement. A case of staphylococcal septicemia was also treated. Repeated blood cultures have been sterile since treatment was started, although his condition is still poor.

Summary

Forty-three cases of pneumococcal and 1 case of streptococcal pneumonia were treated

18.66 Gm. of anhydrous dextrose, 4.18 Gm. of sodium chloride, and 5.76 Gm. of dihydrous sodium citrate per liter of solution. Five of these were iced at the time of collection and nine were at room temperature. There was no apparent difference between these two groups during the experiment, and, therefore, they will be considered as one. Further work has reaffirmed the fact that it is not necessary to refrigerate our solution before use and has shown that it will preserve adult blood up to three weeks without a significant degree of hemolysis.

This group of twenty-five bloods was observed over a period of sixteen days. Eight of them were removed at intervals for attempts at plasma aspiration during this time. Consequently, at the end of the experiment there were remaining ten flasks containing our solution and seven containing DeGowin's. No appreciable hemolysis occurred in any of these bloods. The cell volume was read each day, and the clarity of the supernatant plasma was noted. All of the cell and plasma volumes in the following discussion are based on a total volume of 1,000 cc. The average red cell volume and the degree of clearing of the supernatant plasma in the two solutions during the period of storage are shown in Table 1. The plasma in the flasks containing our solution always had a larger volume and showed more complete clearing at all times during the sixteen days.

The supernatant plasma dilution was aspirated from the 1,000-cc flasks into empty 500-cc transfusovacs by means of a donor valve set that had been altered by replacing the 15-gage venipuncture needle with a square, pointed, 6-inch, 15-gage needle. The rubber stopper in the transfusovac flasks has recently been changed so that there is a thin layer of rubber, continuous with the stopper, closing both the air vent and fluid outlet holes. This new closure is advantageous, for it maintains the vacuum in the flask and the sterility of its contents even though the inner rubber dam has been removed or damaged. In addition, it permits the flask to be filled to the top, if desired, without danger of breaking the sterile seal. Because the rubber closing the fluid outlet hole is heavy enough to make a reasonably tight fit around the aspirating needle, all the air that enters the flask as the plasma is withdrawn must come through the air filter which is placed through the rubber stopper. This enables us to maintain a completely closed system from the time of collection of blood

through to the finished flask of plasma. We have found that it makes no difference in the speed of red cell sedimentation or clearing of the plasma whether or not the vacuum remaining in the flask after the collection of blood is released before storage. Therefore, as is to be preferred, the collections of blood are stored under a vacuum.

In an effort to determine how quickly satisfactory plasma could be obtained, both with regard to clarity and volume, we aspirated one flask of each type at the end of two, four, six, and ten days. None of these had a satisfactory volume, and there were both red cells and large amounts of fibrin present up to six days of storage and considerable fibrin still in the plasma at ten days. Within two weeks after aspiration the fibrin and cells formed a rather heavy precipitate in these plasmas. At twelve days the plasma was reasonably satisfactory, but, because of the greater volume and the appreciably increased clarity of the plasma layer, we feel that fourteen to sixteen days of storage are necessary, preferably sixteen. Continued observation up to twenty-two days has shown but little change in the plasma layer. We attempted to clear turbid plasma solution at the time of aspiration by filtration through the regular filter drip screen (200 mesh to the inch), through a special 300-mesh screen, and through a 3- by 1-inch column of packed wet cotton. None of these seemed to make any difference in the clarity of the product, whether the cloudiness was due to incomplete clearing during early storage or to hypervolemia, which is encountered occasionally in blood from donors allegedly fasting for three or four hours.

There was a distinct difference in the plasma solution prepared from the two preservatives. First, while both usually became crystal clear, that made from collections in DeGowin's preservative solution was not as satisfactory because it almost always had, within three weeks after aspiration, a moderate amount of precipitate, presumably fibrin,² which was of a

A NEW METHOD FOR THE PREPARATION OF DILUTE BLOOD PLASMA AND THE OPERATION OF A COMPLETE TRANSFUSION SERVICE

JOHN B. ALSEVER, M.D., and ROBERT B. AINSLIE, M.D., Syracuse, New York

IN VIEW of the increasing interest in the preparation and therapeutic use of blood plasma and in the preservation of whole blood for transfusions, it seems desirable to present a new method for plasma preparation that involves changes and simplifications in blood bank technique.

During our experiences with the preservation and uses of placental blood,¹ it occurred to us that it might be possible to obtain satisfactory plasma by simply aspirating the clear supernatant layer from the diluted placental blood after a short period of storage. It was found that two weeks was sufficient time for complete settling of the red cells and clearing of the supernatant plasma and that in that length of time no appreciable amount of hemolysis occurred. The use of placental blood is not very practical because of the small amount of blood (average 85 cc) to be obtained by any one collection, therefore we decided to apply this method to adult blood. We believed it would considerably simplify the technique for obtaining dilute, preserved plasma and would make possible a simpler and better system of blood banking. With such a method for taking plasma in good condition from relatively old blood, that most recently collected could always be used for the whole blood transfusions.

In order to make such a method practical it was desirable to devise a technique whereby the whole procedure could be carried out in a closed system, thereby reducing to a minimum the danger of contamination which is present to some degree in all other methods in current use. It was considered that the Baxter transfusovac equipment, with certain slight modifications, would make this possible. A preservative would have to be used which would provide the most effective preservation of the blood during the necessary period of storage and in which there would be a rapid sedimentation of the red cells and sufficient clearing of the supernatant plasma. Otherwise centrifugation would be necessary to

obtain an adequate amount of clear plasma, as is true of simple citrated blood. There were two solutions which, it seemed, might meet these requirements. One was DeGowin's solution,² which undoubtedly is the best blood preservative yet devised, but it has the disadvantage of having to be ice cold at the time of the collection of blood to prevent rather frequent loss due to immediate hemolysis. The other was the solution that we had developed for placental blood. This contained enough dextrose to prevent appreciable hemolysis for three weeks and could be used at room temperature for the collection of this blood. We expected, because of the greater specific gravity of DeGowin's solution, that the sedimentation of the red cells and clearing of the plasma would occur more slowly than in our solution but would permit a longer period of storage. We were not certain of the value of our solution for adult blood or of the time necessary to obtain a clear plasma. Therefore, both solutions were used in the preliminary work.

Twenty-five volunteer donors* were enrolled, and blood was collected after twelve to eighteen hours of fasting. Using the standard Baxter donor valve sets, we drew 500 cc of blood from each donor into 1,000-cc transfusovacs containing 500 cc of preservative†. Eleven of these contained a modification of DeGowin's solution and were cooled to 35°F at the time of collection. We reduced the total volume of preservative recommended for each pint of blood from 750 to 500 cc but maintained the same general proportions, using 40.3 Gm of anhydrous dextrose and 5.76 Gm of dihydric sodium citrate per liter of solution. This meant that we could not expect to keep the blood quite so long as is possible using the larger amount of preservative, for volume seems to be a factor.³ However, the specific gravity of the mixture of blood and solution was not altered significantly, and, therefore, the rate of red cell sedimentation and clearing of the plasma was not affected. Fourteen of the flasks contained our preservative 500 cc in volume, made up of

preservation of the blood or on the quality or the yield of plasma

The recommended technic for plasma production by this method is as follows. A suitable donor is selected by means of a careful history and physical examination. We prefer to use male donors, and they shall have been fasting for at least four hours at the time of collection. The best vein is selected and the arm prepared in the usual manner, using iodine and 70 per cent alcohol. The vein site is anesthetized with 1 per cent procaine solution, and a sphygmomanometer cuff is applied to the arm and inflated to about 50 mm of mercury pressure. A sterile donor valve set is prepared for use, the 1,000-cc transfusovac containing 500 cc of preservative (Fig 1) is agitated thoroughly to wet completely the inner surface, and the metal cap and outer rubber dam are removed. The closed valve is then inserted through the cross mark on the rubber stopper, the point of the needle is placed through the skin, and the valve is opened and closed quickly to produce a slight vacuum in the rubber tubing. (The needle should be held in position during this maneuver to prevent rotation of the bevel for this might interfere with the venipuncture.) Then the needle is introduced into the vein, and blood flows into the tubing at once because of the partial vacuum present. This makes venipuncture simpler and quicker. As soon as blood is in the tubing, the valve is again opened and the flow of blood regulated. During the collection the flask must be constantly agitated to insure proper mixing of blood and preservative. This prevents clotting due to the presence of unmixed blood. When 500 cc has been obtained, the valve is closed and the pressure in the sphygmomanometer cuff released. The needle is now withdrawn from the vein and placed in a clean dry test tube. The valve is removed from the stopper, and the blood that remains in the tubing (about 7 cc) is drained into the test tube. This sample is used for the serologic tests and for blood grouping and cross matching if the collection is to be stored for potential use as whole blood. The flask is now recapped by first replacing the outer rubber dam and then the metal disk and ring. The latter is held in place by adhesive tape. This protects the stopper and keeps it clean. The diluted blood is now gently but thoroughly mixed again, labeled, and placed at once in the refrigerator at 35 F. It remains there in storage for two weeks. During this time the serologic tests will have been done. Be-

tween the fourteenth and sixteenth day, usually the latter, the flask is removed from storage for aspiration of the plasma layer. The cap is removed, the inner rubber dam taken off, and the stopper wiped with 70 per cent alcohol. The vacuum is released by placing an air filter through the fluid outlet hole (Fig 2). This location is used to split the rubber so that the blunt aspirating needle can easily be inserted. The air tube hole is not disturbed, for the passage of any air through it would at once stir up the settled red cells. The air filter is withdrawn from the fluid outlet hole and reinserted through the cross mark on the stopper so that air may enter as the plasma is aspirated. An 18-gage instead of the customary 20-gage needle is used on the air filter because it is strong enough to puncture the rubber stopper easily. A donor valve set with the flat pointed, 6-inch needle is opened, and the long needle is placed through the pierced closure of the fluid outlet hole so that the point is about 1 inch below the surface of the plasma. The closed valve is inserted in an empty 500-cc transfusovac, and the aspiration is begun (Fig 3). At first it can be carried out quite rapidly, but, when the fluid level gets to within an inch of the red cell layer, the speed should be slowed to avoid stirring up the settled fibrin and red cells. The end of the needle must always be kept below the surface of the plasma, for, if much air is allowed to replace the vacuum in the 500-cc flask, the aspiration cannot be completed. A small amount of loosely settled fibrin that lies over the red cell layer (Fig 2) is unavoidably included in the aspirated plasma if maximum yield is desired, for with reasonable care the plasma can be drawn off until only about 75 cc remains over the red cells (Fig 4). The valve is closed as soon as the desired amount of plasma has been obtained, and the aspirating set is removed. If there is question as to the sterility of the collection, the fluid remaining in the aspirating set can be used for cultures.

It is emphasized that adequate refrigeration is essential. The temperature should be 35 F and should not vary more than 2 or 3 degrees. The refrigerator should be roomy and uncrowded and should have a fan to provide circulation of the air and maintain a constant temperature throughout the box. The cooling unit should have a greater capacity than is standard for a domestic refrigerator of the same size because the maintenance of 35 F temperature requires more refrigeration. The unit should be used solely

fairly coarse nature and would not resuspend well. That made from our solution almost always had only a small amount of finely divided precipitate that easily and completely resuspended in the plasma, making it appear as it had on the day of aspiration, and it was too fine to be taken out by the filter drip screen. Second, the yield was consistently larger with our solution. The average for the group from DeGowin's solution was 554 cc and was 615 cc from ours. We compared these amounts with that recoverable by centrifugation of the blood in both solutions. It was found that we were obtaining 86 per cent of the total possible yield from our solution and 81 per cent from DeGowin's. That this 86 per cent yield in our solution is satisfactory is substantiated by the total protein values of the diluted plasma. Duplicate determinations on six flasks by the macrokjeldahl method showed a variation of 2.6 to 2.9 Gm with an average

of 2.8 Gm of protein per hundred cubic centimeters. This means that we are obtaining about 17 Gm of protein in the dilute plasma, and the total present in the serum from an equal amount of blood is only about 20 Gm (using 7 Gm of protein per hundred cubic centimeters and a 43 per cent hematocrit as normal).

Because of the rare appearance of a few small soft clots in the earlier collections, we increased the percentage of citrate in the ultimate mixture of blood and preservative from 0.25 to about 0.4 per cent, and the preservative solution formula is now 18.66 Gm of anhydrous dextrose, 4.18 Gm of sodium chloride, and 8.0 Gm of dihydric sodium citrate per liter, making a slightly hypertonic solution. Since this was done, we have had little trouble with filters becoming clogged by the presence of small clots in the stored blood. This change has had no deleterious effect on the

FIG 5

FIG 5 The addition of merthiolate

FIG 6

FIG 6 The photographic appearance of the dilute plasma now crystal clear after the small amount of fibrin present at aspiration has settled out

but from our experience with preserved placental blood¹ and from work done by DeGowin² we feel that this is not a detrimental factor in the use of preserved blood or the plasma made from it. It has also been demonstrated that there are no reactions peculiar to the use of stored blood.³

Although the small amount of fine precipitate present in this plasma is not therapeutically harmful, it may be the opinion of some that it should be removed. This can readily be accomplished, but it adds to the technical procedures and lengthens the period of preparation to about four weeks. To do this, the plasma from three or four flasks is aspirated into one empty 2,000-cc transfusovac by a technic similar to that described for multiple collections. Merthiolate is added, and the flask of pooled plasma is allowed to

stand at room temperature, whereby clearing occurs more rapidly. This usually takes about two weeks. Then the cleared plasma is reaspirated into the empty 500-cc flasks, leaving all of the precipitate and a small amount of plasma in the 2,000-cc flask. This does produce a more uniform product, there is no precipitate, the agglutinins are, of course, also pooled and their titers in constituent plasmas still further reduced. We have found that pooling will produce a maximum clearing of lipemic plasma.

In July, 1940, a transfusion service was organized for the Syracuse University Medical Center hospitals, and it has been using the new method for plasma production. There are four adjacent hospitals, two general hospitals of 250 beds each and one contagious and one psychopathic unit of about sixty

FIG 3

FIG 3 The beginning of aspiration of the dilute plasma

FIG 4

FIG 4 The completion of aspiration of the dilute plasma

for the storage of blood. A constant temperature cannot be maintained when the door is opened frequently.

It is possible to draw plasma from more than one flask with the same aspirating set without danger of contamination. At the end of the first collection the valve is closed and the end of the aspirating needle pulled up slightly to avoid contact with the red cells. The second flask of blood is prepared as described, using the air filter taken from the first one. The aspirating needle is removed from the first and at once placed into the second. An empty 500-cc flask is opened and the valve transferred from the one just filled. The collection of plasma now proceeds as before. With this method there has been minimum handling of the aspirating set, the needles have touched only the sterile stoppers of the flasks, and their exposure to room air has been only momentary. We have found this procedure satisfactory, and it saves time in making multiple collections and in maintaining the equipment.

The 500-cc empty transfusovacs with the new type stopper will hold the entire yield of plasma from one flask of blood. The possibility of contamination is practically nil if reasonable care is used, because this system is completely closed and only filtered air is

allowed to enter it. However, we are adding merthiolate to a concentration of 1 to 10,000 as is customary with other methods for plasma production.³ This is done by allowing the remaining vacuum to pull the proper amount of a 1 to 100 solution of merthiolate into the plasma from a sterile glycerinated syringe inserted through the cross mark on the stopper (Fig 5). It is likely that this step is not necessary, but, when the plasma is to be stored at room temperature or for long periods, it gives the maximum protection from bacterial growth.³ Now the flask of diluted plasma is closed by the method described for the 1,000-cc flasks of blood, is labeled with the identifying number of the whole blood, and is dated. It is now ready for immediate use or for storage. The maximum safe period of storage seems to be indefinite and is at least two years.³

Except for the presence of lipemia, plasma prepared by this method is quite clear at the time of aspiration and becomes crystal clear after about two weeks (Fig 6), with only the small amount of precipitate described. Its other physical characteristics have been stated, and it is similar to plasma prepared by the method of Elliott.⁴ That there is an increase in the potassium content of the plasma during storage of whole blood is well known,

plasma supply. It means that all routine needs should be anticipated two or three days. Whole blood transfusions are routinely preceded by the infusion of about 200 cc of sixth molar sodium lactate, and about 100 cc more is used to flush the last of the blood through the recipient set. This guards against kidney damage by free hemoglobin released by an unforeseen or accidental hemolytic reaction because it produces an alkaline urine.¹⁷

We find that, as a rule, friends or relatives of the patients appear in sufficient numbers to supply more than enough blood to replace the amount used. There are, of course, a few patients who can neither supply a voluntary donor nor afford a professional one. These we care for, if need be, through a number of volunteer donors whom we have listed according to their blood groups. We also have a list of professional donors who are readily available for those who desire them.

Blood is drawn in the manner described previously for plasma preparation. All routine collections are made in the 1,000-cc flasks containing the preservative. To supply requests for fresh blood, we use the regular 500-cc transfusovac or the 250-cc centrivac, depending on the amount wanted. Fresh plasma is prepared by centrifugating freshly collected blood for one hour at 2,000 revolutions per minute. It is then allowed to stand in the refrigerator long enough so that the swirl of cells, which sometimes occurs when the centrifuge stops, will have settled out. The clear supernatant plasma is then aspirated into the 500-cc plasmavac which contains 250 cc of isotonic saline as the diluent. Un-

diluted plasma is made in the same way, except that it is aspirated into an empty flask. We prefer to collect blood for these two purposes in the centrivacs because they can be placed directly into the centrifuge and the plasma can be aspirated by the same closed technic described for the 1,000-cc flasks. Elliott's original method⁴ can be used if centrivacs are not available, but it is neither as easy nor as safe from contamination as the centrivac method. All fresh blood and plasma are used as soon after preparation as is possible and are stored at 35 F during the interval. We feel that twenty-four hours must elapse before such preparations are to be considered no longer fresh.

Donors are questioned as to their fasting state, and all the necessary information is obtained and recorded on the donor card (shown in Table 3). They are required to sign the statement on the reverse side of the card (lower half of Table 3). This avoids any possible difficulty in the future use of the blood. The test tube containing the 7 cc of blood, collected as described earlier, is centrifuged, and enough serum is pipetted off to do an emergency flocculation test and to fill two capillary pipets for use in subsequent cross matching. Red cells are taken from the clot, the donor's blood group is determined, and a fairly heavy suspension of cells is made in a small, properly labeled test tube containing about 1 cc of the preservative. The capillary pipets of serum are placed in this tube which is then attached to the flask of blood by a rubber collar (Fig 7). In this manner the cells and serum from each blood are kept constantly with the proper flask and

beds each. The transfusion laboratory is located in one of the general hospitals, has its own staff, and operates on a twenty-four-hour basis. All of the blood is collected and stored in the laboratory, and blood or plasma is transported to the other hospitals of the group in canvas carrying bags. The service is prepared to furnish fresh blood, preserved blood, fresh plasma (either diluted or undiluted), and dilute preserved plasma. The indications for the use of fresh blood or fresh plasma are the blood dyscrasias and infections. Undiluted plasma is used in the treatment of edema in the presence of a low blood protein level. Preserved blood and diluted preserved plasma¹ are satisfactory for most other conditions. We consider that a significant degree of anemia is the principal, if not the exclusive, indication for the use of whole blood. All types of shock, even in the face of profuse hemorrhage, can and should be treated with plasma until the state of shock is relieved. Then, if sufficient anemia is present, whole blood can be administered. However, it is clinically obvious at times that red cells are needed. Dilute plasma is preferable for the treatment of shock because it can be used in any required amount, does not

need grouping or cross matching, can be given much more rapidly than whole blood because of its lower viscosity, and supplies needed fluid and electrolytes as well as blood protein. For emergency use we maintain a supply of plasma and a set for its administration in each operating suite, emergency receiving room, and the obstetric delivery suite.

The regulations governing use of the service are designed to aid its efficiency. A requisition card (shown in Table 2) must be filled out by the physician in charge of the case and sent to the laboratory with 5 cc of the patient's blood. He also arranges for a suitable number of donors to come to the laboratory to give blood at one of the periods regularly designated for that purpose. Prospective donors are instructed to report after having fasted for at least four hours. Special arrangements are made for those few who cannot come at a regularly scheduled time. Donors for emergency use are taken care of at any time. Except for emergencies, no blood or plasma is issued outside of regular laboratory hours, and donors are to be sent in to replace the amount requisitioned prior to the expected time of use if possible. Thus we find maintains an adequate whole blood and

Every effort is made to exclude pyrogens from our equipment by using the Vacolter solutions for infusions and by having the collection of blood and the maintenance of all equipment used in the transfusion work supervised and done in one place. Only freshly distilled water and fresh, sterile isotonic saline are used in cleansing and preparing the equipment. Tap water is never used for such purposes.

During the first three months of this service we gave over 300 transfusions of the various preparations of blood and plasma with no adverse reactions. Sixty-five flasks of the dilute preserved plasma have been used with excellent clinical results.

Conclusions

We have described what might be considered a complete transfusion service. It has all the advantages of a simple blood bank and also supplies fresh blood, fresh plasma (whole or dilute), and preserved diluted plasma. It provides a valuable store of preserved blood and plasma for emergencies and a new plasma method that utilizes the older collections, eliminates centrifugation, and makes possible the routine use of the freshest blood in each group for whole blood transfusions. The preservation of blood is

certainly advantageous in emergencies, but the shorter the period of whole blood storage the better it will be as such for therapeutic use. We have found that with this technique the preserved blood that we use for transfusions is rarely over four days old, and the exceptions that do occur are usually with bloods of the two rare groups.

The new method for the preparation of dilute blood plasma which we have presented has proved entirely satisfactory. It is easier, cheaper, and safer than any method yet described. It enables any hospital to prepare plasma with a minimum of equipment. The method should be of particular value for the small hospitals and for mass production for military use.

COURSE ON THE TREATMENT OF COMMON DISEASES

Dr. Clayton W. Greene, of Buffalo, has arranged a course on the treatment of common diseases for the Saratoga County Medical Society at the Saratoga Hospital in Saratoga Springs. All the lectures have and will be given at 3:30 p.m.

The following have been completed: November 27, 1940, "Treatment of Precordial Pain," Dr. Clayton W. Greene, December 4, "Treatment of Dyspnoea," Dr. Frederick T. Schnatz, December 11, "Treatment of Low Back Pain," Dr. Frank N. Potts, December 18, "Treatment of Epigastric Distress Following Meals," Dr. A.

H. Aaron, January 8, 1941, "Treatment of Common Skin Lesions," Dr. Earl D. Osborne, and January 15, "Results of Modern Methods in the Treatment of Anemia," Dr. Francis D. Leopold, all of Buffalo.

On January 22, Dr. Arthur Purdy Stout, of New York City, will discuss "Problems in Tumor Diagnosis," and on January 29 "Problems of Gastric Cancer" will be given by Dr. Harold D. Harvey, of New York City.

The last two lectures in this course (the ones on malignant disease) are given in cooperation with the State Department of Health.

COURSE ON PEDIATRICS

Dr. Charles Hendee Smith, professor of pediatrics, New York University College of Medicine, New York City, has arranged a course on pediatrics for Chemung County Medical Society. The lectures are held at the Mark Twain Hotel, Elmira, at 6:30 p.m.

On January 8 "The Pneumonias of Childhood" were discussed by Dr. Charles Hendee Smith. The following lectures are still to be given: February 12, "Rheumatic Fever, Chorea and

Heart Disease," by Dr. Katherine Dodge, professor of pediatrics, New York University College of Medicine, and March 12, "Preventive Pediatrics and the Periodic Health Examination," by Dr. Gaylord W. Graves, clinical professor of pediatrics, New York University College of Medicine.

A last lecture in this course (one on "The Growing Feet of Children") has not been definitely arranged.

FIG 7 Flask of freshly collected blood (in preservative) showing the tube containing the cell suspension and the capillaries of serum attached to the flask

are readily available for cross matching. The remainder of the 7 cc of blood is sent on for the routine serologic tests, which are those approved for the Public Health Laboratories of the State of New York. All collections are numbered serially, and each number is preceded by the blood group letter (Landsteiner), which gives each one an identifying unit number. This, together with the above data concerning the blood and the name of the person who does each test, is recorded on the donor card. The results of the regular serologic tests are added as they are reported to us. Each flask of blood is marked with the donor's name, date, and the unit number. The completed donor cards are filed according to the blood group. When a collection of blood has been stored for fourteen to sixteen days, the plasma is drawn off and the donor card is placed in the plasma file. It is possible to increase the preliminary storage period to twenty days if necessary.

In order to facilitate the utilization of blood collections, we perform a rapid flocculation test for evidence of syphilis. This is a procedure devised by Dr O D Chapman, and it has been used here in Syracuse in its present form as an emergency test for the past two years.* It is simple, safe, easy to

read, and takes only about twenty minutes to carry out. This test is done on all of our collections. We do it as many times a day as is necessary to make blood available for use, and we have found it exceptionally satisfactory.

On receipt of a requisition card, if it is felt that the indications for the kind of blood or plasma requested are not clear, the case is discussed with the physician-in-charge before approval is given. If whole blood is needed, the patient's blood group is determined, the proper kind of a homologous blood is obtained, and the two are cross-matched. These data and the unit number of the blood to be used are recorded on the reverse of the requisition card and signed by the person doing the tests. The recipient's name, hospital, and ward or room number are entered on the back of the donor card. If plasma is required, the proper kind is obtained and the same data are recorded on the two cards (except that grouping and cross matching are not necessary). The blood or plasma, with the requisition card and a filter drip venoclysis set, is sent to the patient's ward at the time requested. The physician giving the transfusion must fill in a report in the space provided on the back of the requisition card with a detailed description of a reaction, should one occur. All reactions are investigated by the service, and a complete rechecking is made if necessary. The requisition card is returned to the laboratory and is joined to the proper donor card. The two are then filed under the patient's name.

All of the grouping and cross matching is done by the vaseline sealed, hanging drop method and must be observed for thirty minutes, with a minimum of twenty permissible in emergencies. The so-called "universal donor" blood is only used in case no homologous blood can be made available. We do not allow the heating of any blood or plasma before or during its administration and wish to emphasize that this applies to these fluids after refrigeration. That even extremely cold blood is not harmful and that warming it causes some reactions have been demonstrated.^{1,2} All transfusions of whole blood are begun slowly at not more than 60 drops a minute for the first fifteen to twenty minutes. After this period, when the greatest danger of a serious reaction has passed, the rate of flow can be speeded to suit the needs of the case. Plasma may be given as rapidly as seems necessary, since no reactions (except those due to pyrogens) have been reported with its use.

* The technic is soon to be published

(2) The results of agglutination tests are not conclusive Eagleton and Baxter,² Hammerschmidt,³ Ewing,⁴ Nishimoto,⁵ Murray,⁶ Robinson and Peeny⁷ divided the diphtheria group into at least ten to fifteen different serologic types with a number of strains, either remaining outside of these groups or being magglutinated altogether. The serologic individuality of the bacilli is nearly as strongly marked as with influenza bacilli. No sign of real type differentiation appears to be connected with the agglutinative type. The same is to be said about complement-fixation, attempted by Bandi⁸ as early as 1903, by Menton, Cooper, and Fussell⁹ in 1933, and by Labranca¹⁰ in 1938. All these serologic reactions do not appear to be characteristic of biologic types and are not stabilized. No less unstable and of no greater value in differentiation are the hemolytic and hemodigestive qualities of diphtheria bacilli and their different behavior toward different sorts of blood.

Type-specific polysaccharides have been recovered by Chinese authors (Wong and Tung¹¹). These products behaved like polysaccharides of pneumococci, being antigenic and giving specific reactions in precipitation and absorption tests, however, the principle was not applicable to differentiation, as these sugars happened to occur in different groups even in diphtheroids.

(3) The existence of type-specific bacteriophages has been claimed by Keogh, Simmons, and Anderson¹² in Melbourne (Australia, 1938). These authors found two kinds of bacteriophages in cultures, they conclude from their experiences that there may be differences in the susceptibility to and the originating of phages in different cultures, as Stone and Hobby¹³ demonstrated in 1934. The Australian authors connect those differences with group differentiation. It is yet too early to judge these data in spite of the large number of strains investigated.

(4) Diphtheria bacilli may be cultivated in a variety of mediums, and in many of them they show differences of growth. In broth we see cultures thoroughly turbid, others with clear fluid and pellicles on the surface, still others with granular deposits. The formation of pellicles is often regarded as an indicator of good toxin-producing power. In 1931 Dimitrijevicz-Speth and Jovanovic¹⁴ claimed that strains coming from cases with laryngeal stenoses always made the broth turbid, while other strains growing in broth left the fluid clear. On plates of agar, or blood plates, or on those of very poor mediums, one meets dif-

ferent forms of colonies like the well-known rough and smooth forms of other bacteria. Hammerschmidt,¹⁵ as early as 1924, described three different colonial forms obviously corresponding to the newly reported colonial forms of English authors. In 1928 Parker¹⁶ differentiated on trypsin-serum-agar plates the light growers with normal toxogenicity, the rough heavy growers with little toxogenicity, the smooth heavy growers with high toxogenicity. The use of tellurite, initiated by Conrad¹⁷ (1912), aimed at the differentiation from diphtheroids and was widely utilized (like the addition of cysteine) for the improvement of diphtheria mediums. Other methods referred to carbohydrate fermentation. The results seemed to be contradictory within the diphtheria group itself but rather uniform for the separation of the diphtheroids. This method is now again becoming more valuable in the differentiation of diphtheria types, although Frobisher¹⁸ recently emphasized that no well-differentiated biochemical groups were revealed by his careful studies.

Finally, there are studies of the metabolism of the bacilli and the use of synthetic mediums. These studies go back to Uschinsky¹⁹ in 1893. Good work has been done by Braun and Hofmeyer,²⁰ who were successful in obtaining synthetic mediums and who studied the food-stuffs that were vitally needed. They found pretentious and unpretentious varieties among these strains and noted this as a matter of physiologic interest and not of differentiation.

In this country Pappenheimer, Mueller, Cohen, Evans, Happold,²¹⁻²⁴ and others recently reopened these studies with synthetic mediums using a series of amino acids, lactic acid, cysteine, and traces of heavy metal ions. They obtained toxin production, but they admit that optimum conditions for practical application and for the use of all strains have not as yet been developed.

In their excellent work Anderson, Happold, McLeod, Cooper, and Thomson^{25, 26} took advantage of these methods of differentiation. They used a tellurite agar containing boiled blood (chocolate agar) for colonial form and examined growth in broth, alkali production, sugar fermentation, and hemolysis. In this manner three forms were differentiated.

CURRENT PROBLEMS IN DIPHTHERIA

ERICH SELIGMANN, M D , New York City

DIPHTHERIA is one of the best studied communicable diseases. The etiologic agent is known, and the mechanism of its pathogenicity through the production of toxin is well understood. Effective treatment by antitoxin is available. Attempts to free mankind from this disease through specific prophylaxis, especially by means of active immunization, have been promising. Nevertheless, many unsolved problems remain which arise with renewed emphasis from time to time. Thus, epidemiologic, therapeutic, and immunologic considerations are under discussion now as they have been in the past.

The severity of the disease changes continuously in different countries, rising here and falling there, and the evolution of the morbidity curve in a given country is more or less an object of speculation. We are in no position to undertake experimental epidemiologic studies such as have been made with mice in other infectious diseases, since animals spontaneously susceptible to diphtheria are not known. Climate, latitude, standards of living, heredity, artificial immunization, all these factors seem to influence the spread of the disease. From a historical point of view, times of no interest (almost no knowledge of the disease) alternated with times of the greatest concern. Some countries were ravaged by severe, long-lasting epidemics, and other countries were almost completely spared. The ingenious assumption of Gottstein,¹ which, in addition to seasonal and annual periodicity, calls attention to the existence of so-called secular curves of diphtheria, though very interesting, fails to provide us with more than a statement of facts.

The shift in age distribution in many areas has been ascribed to social factors as well as to increased artificial immunization. The latter, however, as judged by antitoxin level or negative Schick reaction, is not always concomitant with insusceptibility to attack. Strangely enough, there is even doubt as to the development of immunity following recovery from the disease.

Two topics seem to us of particular significance in attempts to explain the epidemic waves of diphtheria.

- (I) The bacteriologic differentiation of *Corynebacterium diphtheriae* as related to clinical and epidemiologic observations
- (II) The manifestations of immunity, especially the so-called natural immunity, as shown by specific immune reactions

I—Modern bacteriology is inclined to divide a given bacterial species into type strains that differ in serology, morphology, or biochemistry, with a view to correlating such differences with the pathology and epidemiology of the disease. The majority of pathogenic bacteria and viruses are now being considered in this way. By way of reference to the pneumococci, *Salmonella* group, bacilli of dysentery, encephalitis, and influenza viruses, it is obvious that some progress has been made.

Attempts have been made along similar lines with the diphtheria bacillus for almost fifty years, previously in order to separate the diphtheroids from the diphtheria bacillus, later to subdivide *Corynebacterium diphtheriae* itself. Some of the most frequently used methods of differentiation related to (1) virulence and toxin production, (2) serologic tests, (3) bacteriophage activities, and (4) cultural characteristics and metabolic activities.

(1) *Virulence* as determined in guinea pigs or rabbits is variable. The occurrence of avirulent forms is beyond doubt, but one may find virulent and avirulent strains side by side in the same patient. Slightly virulent or avirulent strains with some unusual morphologic features may be recovered from convalescents. This leads to the fundamental question already asked by Roux and von Behring: "Is there a transformation from the real Diphtheria-Bacillus to the Diphtheroids during recovery of the patient?" We are not sure that virulence in guinea pigs and in man are the same, but we must admit the occurrence of all grades of virulence in real diphtheria bacilli and the loss of virulence in cultures (we have no knowledge of acquisition of virulence by nonvirulent strains). As a method of differentiating strains or types such differences are of no value. The experiences with diphtheria toxin are very similar. Existing differences in toxin production, such as they are, do not help in a differentiation within the group.

From the Delamar Institute of Public Health and the Department of Bacteriology, College of Physicians and Surgeons, Columbia University

In this country information has come mainly through the work of Frobisher,^{39 40} in Baltimore, who pointed out interesting contrasts as to biologic properties of the bacillus and type incidence in different parts of this country. The following generalization seems permissible. In countries with widespread epidemics and severe outbreaks the existence of sharply differentiated types of diphtheria bacilli, often clinically in agreement with the nomenclature of the British authors, is readily confirmed. In countries with mild epidemics and low morbidity, difficulties in differentiating types are often encountered, and, if types are found, they do not seem to be of any clinical significance. In such areas one observes many avirulent and atypical strains that cannot be classified as belonging to any one of the described types. Such deviations have also been described in Germany, England, and elsewhere. Wright and Christison,⁴¹ for instance, enumerate six instead of four types, and other workers suggest that there may be many more.

Opinions differ as to the clinical importance of the types irrespective of their epidemiologic distribution. Clauberg⁴² once proposed that the mitis type in carriers was insignificant from the public health point of view, a suggestion which has found no support anywhere. There are other authors who deny any correlation with clinical findings. Gundel,⁴³ in Germany, claims that 46 per cent of his gravis strains were found in mild cases. Many experienced workers have observed very severe and fatal cases in diphtheria caused by the mitis type. In consequence of these contradictions, some authors propose to do away with the terms gravis, mitis, and intermediate and to replace them with letters A, B, C, or with figures I, II, III, etc. (Stuart,⁴⁴ Gundel,⁴³ and von Bormann⁴⁵ a o.)

The status of the atypical or indeterminate strains is as yet uncertain. Frobisher is absolutely right in stressing the necessity of agreeing upon type characterization. But these characteristics seem to vary in different countries, epidemics, and laboratories according to the type of mediums used. More than half a dozen suggestions have been offered for suitable nutrient mediums. The differences concern methods of preparation, such as the kind of agar base, the sort and treatment of blood, the presence or absence of tellurite, etc. Not a few authors emphasize that no reliance can be placed upon the appearance of sharply differentiated colonial

forms and that preference should be given to the starch-fermentation reaction as a more reliable test, other workers have more confidence in the type of growth in broth or in a combination of several methods of differentiation. Frobisher insists that all seven described characteristics must be present to classify a strain as a gravis type, von Bormann, on the other hand, does not believe in this classification because these seven characteristics are not always present. We may well appreciate the difficulties when we learn that the famous Park-Williams Number 8 strain, cultured in most of the world's laboratories, has been classified as a mitis as well as an intermediate!¹

The question therefore arises: Are these types really established types or are they "Standorts-Varietaeten" (variants locally restricted), do they remain the same under observation in cultural mediums, in the body of animals, and in human beings? A number of variations has been described by many authors, rough and smooth dissociation, papilla formations, etc., but the few authors who have worked with single-cell cultures insist upon the stability of the types *in vitro*. As to stability in the body, one is reminded of the older publications of Bernhardt,⁴⁶ and it seems that these experiments should be continued. The observations made by Weigmann and Koehn,⁴⁷ that types may change *in vitro* when in contact with human saliva, are not convincing. Those adhering to the point of view of variability must bring the burden of proof. Up to the present the more orthodox concept prevails.

Observations of great interest were made in groups of individuals. Members of the same family usually carry the same type, patients as well as healthy carriers. The recovered patient generally has the same type at various intervals. But there are exceptions. From 5 to 10 per cent of the convalescents show a change of type at home, or two types occur at a later date. These figures rise to 25 per cent and more if patients are held in diphtheria wards and to 68 per cent if patients remain longer than two months in these wards (Glass and Wright⁴⁸). It was concluded that these changes do not indicate the occurrence of variation or mutation but are the result of cross infection much more frequent in hospitals than in homes. The British authors have, therefore, demanded that special wards be assigned to gravis-infected patients. Under such a regimen the duration of the carriership may be shortened, new infection with other

ment starch, morphologically long rods with well-marked granules

- (3) Fine growth of flat colonies with black center and translucent margin, granular growth in broth, morphologically barred bacilli with variable amount of granules

When a systematic effort was made to correlate the occurrence of these types with clinical and epidemiologic observations, it was found that the first organism was isolated mostly from severe cases, the second was more frequently recovered from mild cases, and the third again most frequently from the severe cases of the disease. The statistical data appeared to be convincing. In a first survey of 1,500 diphtheria cases they stated a lethality of 15 per cent in cases with the first organism, 0.5 per cent in cases with the second, and 7.5 per cent in cases with the third. Thus, they felt justified in designating as *gravis* the first type, as *mitis* the second type, and as intermediate the third type. In Germany, where the numerical incidence of types has been carefully checked in times of rising epidemics, differences varying from 40 to 80 per cent *gravis* have been observed in different localities (Pesch,²⁷ in Cologne, Schiff and Werber,²⁸ in Berlin). All three types have been found in the more widespread epidemics, whereas in an outbreak of a localized character in almost all instances not more than one single type has been recovered. The patient, as well as his contacts, carried the same type until recovery, although there are some exceptions.

Pathologic, anatomic, and statistical investigations indicate that special symptoms apparently coincide more or less frequently with the types. In a review issued in 1936²⁹ and covering more than 6,000 of these cases, the English authors summarize these data as follows:

	<i>Gravis</i>	<i>Intermediate</i>	<i>Mitis</i>
Lethality	13.3%	8.6%	2.3%
Paralysis	17%	9.9%	4.5%
Croup	2.3%	1.3%	7.5%
Hemorrhages	3.5%	3.7%	0.4%

More recently, McLeod and his collaborators,³⁰ investigating autopsy findings on a large scale, emphasize that *mitis* may be a mighty producer of large membranes, *gravis* working more in an inflammatory way and as a cause of lung complications. Therefore, the assumption seems to be justified that these types are independent characteristic types within the species *Corynebacterium diphtheriae*.

All types produce toxins that are qualita-

tively identical. The *mitis* seems to be the best toxin producer of all, in spite of its lower aggressiveness (Parish, Watley, and O'Brien³¹). Virulence in guinea pigs and rabbits is proved in each of the groups, although sometimes failing in *mitis* and intermediate, whereas virulence is almost regularly present in the *gravis*. *Gravis* bacilli are more frequently found postmortem in man than either of the other types (McLeod, Orr, and de Woodcock³²). The same is true following experimental inoculation of guinea pigs (Zinnemann and Zinnemann,³³ Robinson and Marshall³⁴). If this were a sign of higher invasive power, it might be checked by special experiments. Gundel and Erzini³⁵ infected guinea pigs with *gravis* and *mitis* strains and sometime later injected them with diphtheria antitoxin. They were able to protect the *gravis*-infected animals from death only if the serum was administered within eight to twenty-four hours after infection, the *mitis*-infected animals still survived when protective doses of serum were given as late as ninety-six to 144 hours after infection. Preventive doses of serum proved efficient for a period up to ten days before infection with *gravis* and up to twenty days with *mitis*. Even in human beings the *gravis* and intermediate seem to overcome immunity to a greater extent than the *mitis*. Thus, in Cork, Leeds, and Manchester the strains recovered from so-called immune or immunized persons belonged to *gravis* type in 107 cases, intermediate type in 20 cases, *mitis* type in 8 cases, and atypical form in 1 case, or of 2,103 *gravis* cases, 5.1 per cent occurred in immunized (of these fatal or severe 2.4 per cent), of 815 intermediate cases, 2.5 per cent occurred in immunized (of these fatal or severe 1.1 per cent), of 916 *mitis* cases, 1.3 per cent occurred in immunized (of these fatal or severe none).³⁶ And if we add that (according to Weiland and Leinbrock³⁶ in 1939) resistance against heat and disinfectants decreases from *gravis* to intermediate to *mitis*, we seem to have a clear gradation—*gravis* and intermediate as the more formidable organisms with greater invasive power, greater resistance, and perhaps, as has been assumed but not yet proved by the British authors, with some enhancement of their toxin-producing ability. On the other hand, new experiments with spermophils (Dimitrijevicz-Speth and Arsenijevicz³⁷) and white mice (Zinnemann³⁸), however, show that the pathogenic potency of the three types in these animals does not correspond with their behavior in man or guinea pigs.

ical latitude, and racial differences. We may be certain only that occurrence of antitoxin is more frequent in adults than in young children and that the incidence of diphtheria is the reciprocal of this. However, this parallelism need not reflect cause and effect, the more so since we know of diseases that exhibit no difference in age selection in spite of an increase in antibodies with age. The same is to be seen in animals that are not at all susceptible to diphtheria but that show a similar increase of antibodies with age. The more widespread the disease is, it was claimed, the greater is the opportunity of contact with diphtheria bacilli and of the acquisition of immunity through inapparent infections. This general statement, however, fails to explain the increase of diphtheria over a large number of years in certain countries and the spectacular decrease at the same time in other countries.

Since the famous investigations of Zingher, Park, and others, it is generally known that in civilized countries the children of the well-to-do possess less diphtheria antitoxin than children of the same age of lower social standing. It has been taken for granted that more densely populated urban areas show invariably higher amounts of antibodies than thinly populated rural ones. Not so long ago, however, observations by Chason⁶² in rural Alabama proved a higher percentage of Schick-negative children in the less dense areas. In these areas 68 per cent of 6-year-old children and 92 per cent of ten-year-old children were negative,* figures even higher than they are in metropolitan congested areas.

Diphtheria is a disease of the temperate zones, decreasing toward the equator and toward the poles. For a long time the disease was not believed to exist at all in the tropics or in the arctic regions. On the other hand, there are numerous observations of a very high percentage of negative Schick reactions and of circulating antitoxin in natives of tropical countries, these natural antibodies also occur in populations of islands in the northern zones. A report of 100 per cent negative Schick reactions in inhabitants of the island of Koguljew (69 degrees northern latitude) is accompanied by the statement that there are neither diphtheria cases nor carriers in this isolated population (Asbelew and Margo⁶⁴). Summarizing the very large number of observations† and comparing them with the figures coming from countries with

widespread diphtheria, we find that in the temperate zones immunity increases up to the fifteenth to eighteenth year of life, reaching an endpoint of about 70 per cent in adults, in tropical countries such amounts are already reached in the fifth year of life, and the adult endpoint is as high as 90 to 100 per cent. In the Arctic zone the increase of antibodies is generally slower with age, and the level reached in adults rarely surpasses 60 to 70 per cent. The amazing fact therefore emerges that in countries where the incidence of diphtheria and the occurrence of diphtheria bacilli are very rare natural immunity is either extremely high (tropics) or not much lower than in the Temperate Zones (Arctic zone).

Several theories have been advanced to explain this aforementioned fact: (1) differences in racial susceptibility to diphtheria and in individual ability to produce antibodies, and (2) climatic influences on the host or the operation of other exogenous factors on diphtheria bacilli transforming them into harmless saprophytes without loss of antigenicity. Both possibilities seem to be of some significance. Observations on white people in tropical countries and on colored people in the United States point to differences of races, but no definite decision has as yet been arrived at. On the whole, the observations agree upon a lower percentage of immune white people living in the tropics as compared with the native population, in this country, however, Doull⁶⁵ claims to have obtained more positive Schick reactions with Negroes in Baltimore. A purely racial influence does not seem to be buttressed extremely well, climatic and social conditions apparently being of greater importance. Thus, in Baltimore the morbidity of the Negroes, in spite of a lesser degree of natural immunity, stands below that of the white population (Doull), in New York, on the contrary, a distinctly higher morbidity among Negroes has been demonstrated by Emerson.⁶⁶

In addition to the facts already discussed, it is interesting to note that authors like von Gröer and Kassowitz,⁶⁷ Friedberger, Bock, and Fuerstenheim,⁷⁰ and Hirsfeld⁷¹ consider normal antibodies a consequence of physiologic processes and a function of age or serologic maturation rather than an effect of immunization of any kind. Factors of heredity were taken into account by Eigenbrodt⁷² in relation to susceptibility and by Park, Zingher, and Serota⁷³ in relation to Schick reaction. Hirsfeld postulated the existence of some relationship between blood groups and the

* Recently confirmed by Gill.⁶³

† See Ramon⁶⁸ and Jensen.⁶⁹

types may be prevented, and perhaps the dreaded return cases may eventually disappear.

To summarize The differentiation of diphtheria types is most important from the point of view of bacteriology, pathology, and epidemiology, but the wide variations obtained by observers in different localities make it difficult to define any basic standards. Moreover, the extent of epidemics, as well as climatic factors and the intervention of host resistance, may have some influence upon the germ's "phenotypus."

II—Problems of immunity rank next in our discussion. Admittedly, passive administration of antitoxin is a certain preventive against the disease, and active immunization seems to be very successful, especially in this country. This success has been determined not only by the trend of morbidity and mortality but is also corroborated by the results of immunologic tests. The presence of antitoxin in the blood and a negative Schick reaction are customarily looked upon as a gauge of the efficacy of immunization. The same biologic tests have been taken as criteria of protection of whole population groups not subjected to artificial immunization, assuming that the appearance of antibodies in such instances is the result of repeated subclinical infections. Schick reaction, presence of antitoxin, and susceptibility are all mentioned in the same breath, but the causal relationships between these factors have not been conclusively proved.

Three questions must, therefore, be answered (1) Is there any demonstrable immunity after recovery from the disease? More than twenty years ago I postulated that no such immunity exists. The frequency of second clinical attacks, as well as the failure of consecutive immunologic responses, argues against such an assumption (Seligmann⁴⁹). As early as 1916, Park and Zingher⁵⁰ found that more than 65 per cent of diphtheria convalescents were Schick positive. Recent investigations have confirmed this observation (Rosling⁵¹). Vejnar⁵² reported that natural increase of antitoxin develops more slowly in convalescent children within the next two years than in children of the same age who did not have the disease. Therefore, the majority of convalescents possess neither antibodies nor show a negative Schick reaction.

(2) Does the Schick reaction run parallel with antibody titer? It was formerly assumed that a negative Schick reaction was observed when a certain minimum amount of

antibody exists in the blood, and the level was established at about 0.01 to 0.03 units per cubic centimeter of serum. Today we know that this is not correct. Antibody titer can differ in the blood and in the tissues. Sensitiveness of the skin, as well as physiologic fluctuations (menstruation), also plays a role (Jungeblut and Bailly⁵³). Newborn babies and infants invariably exhibit negative Schick reactions in the absence of the slightest trace of antibodies (Okell,⁵⁴ Glenny⁵⁵). Magara⁵⁶ found negative Schick tests in young children in which the antibody level was less than $1/200$. An incapacity to react on the part of the child's skin may explain some of these observations, but even in older children significant differences have been reported, especially in vaccinated children. Bundesen⁵⁷ saw negative reactions with less than $1/250$ unit per cubic centimeter, and Parish, Edin, and Wright⁵⁸ found Schick negativeness with antitoxin titers even below $1/500$ unit per cubic centimeter. They concluded, as did Jensen,⁵⁹ that negative Schick reactions may occur with less than $1/2,000$ antitoxic unit in the blood of immunized persons. "There is no fixed antitoxin titer at which individuals pass from the negative to the positive group, or vice versa." Finally, Sigurjonson,⁶⁰ referring to varying susceptibility of the tissues, claimed that in a transition zone of 0.004 to 0.01 antitoxic units per cubic centimeter of serum positive as well as negative reactions may be possible. We know that even this broad transition zone is too narrowly limited. The only fact that can be asserted with certainty is that the average titer of antitoxin is higher in Schick-negative than in Schick-positive individuals.

(3) Does a negative Schick reaction and an established antibody titer mean clinical protection? As a matter of fact, attacks of diphtheria have been observed in individuals with a high amount of antitoxin in the blood, resulting either from natural or artificial immunization. Not long ago Procházka⁶¹ reported diphtheria in about 40 persons who had from $1/25$ to 1 unit before their attack. Moreover, hundreds of cases have been reported among successfully immunized children.

It becomes clear that certain epidemiologic questions in diphtheria require further study before one can say whether acquired protection is specific or nonspecific in character. Thus, the appearance of antitoxin or a turn in the Schick reaction have been correlated with age distribution, morbidity rates, economic level, density of population, geograph-

STREPTOCOCCUS VIRIDANS PNEUMONIA

Report of Eight Cases

FRED F SENERCHIA, JR, M D, and HORACE R LIVENGOD, M D, F A C P,
Elizabeth, New Jersey

IT IS our impression that many practitioners feel that any *Streptococcus viridans* infection is invariably fatal. Since we are unable to find any case reports in the American literature on *Str viridans* pneumonia, it may be of interest to report 8 cases.

During the early winter of 1939 in a series of 36 consecutive pneumonias at the Elizabeth General Hospital and Dispensary, 8 cases reacted atypically and were found by sputum culture to be *Str viridans* pneumonias.

While we realize that a diagnosis of *Str viridans* pneumonia from sputum culture alone may be cause for criticism because the organism is occasionally found in routine throat cultures, yet we feel that the following observations justify the diagnosis:

- (a) Atypical clinical course of the pneumonia
- (b) Absence of typing with all available types of pneumococcus
- (c) Absence of response to sulfapyridine
- (d) Florid growths of *Str viridans* from all the sputums except in 1 case in which there were growths of both *Streptococcus hemolyticus* and *Str viridans*
- (e) Florid growth of *Str viridans* from pleural exudate in the only case in which thoracentesis was indicated

In each of these cases routine orders of the medical service were carried out as follows: (1) sputum typing, (2) blood culture, (3) complete blood count, (4) urinalysis, (5) x-ray of chest, and (6) sputum cultures for nonpneumococcal pneumonias. These orders were carried out on all of the cases except 1 in which the patient expired before an x-ray was obtained.

Case Reports

Case 1—A. S., a white man, aged 29, first became ill six days prior to admission, at which time he complained of pain in the chest and cough. He was under the care of his family physician for several days and, showing no improvement, was hospitalized. On admission the chest observations were not distinct. On the

following day, however, there were increased voice sounds and rales over the left base. These observations were corroborated by x-ray. The Neufeld reaction for all available groups done on the day of admission was negative. The white blood count was slightly elevated, and the urine showed nothing unusual. Serology and blood cultures were negative. The sputum was rusty colored and negative for tuberculosis. Three hundred grains of sulfapyridine were given, a small amount of it by rectum because of the extreme nausea. The highest temperature was 104.8 F. This gradually came down by lysis and became flat on the twenty-seventh day of hospitalization. He was discharged in good condition on the thirty-sixth day of hospitalization. The pneumonia was of the lobar type. Sputum culture on the nineteenth day of hospitalization revealed a florid growth of *Str viridans*.

Case 2—J. LeM., a white man, aged 45, became ill three weeks prior to hospitalization with cough productive of yellowish sputum, malaise, difficulty in breathing, and lack of appetite. Upon admission his temperature was 103 F. Physical examination showed a definite lag of the left chest. There was no evidence of any consolidation. However, there were high-pitched sibilant rales throughout the entire chest, with moist rales at both bases posteriorly. X-ray revealed a mottling of both lungs resembling a nontuberculous infection. The Neufeld reaction with all available groups was negative. The white count on admission was 17,300 with 79 per cent polymorphonuclears, 10 per cent lymphocytes, 2 per cent monocytes, 1 per cent eosinophils, and 8 per cent stab forms. The red count showed nothing unusual. Sputum smears were negative for pneumococci and tuberculous bacilli. Sputum cultures showed a florid growth of *Str viridans*. Blood cultures were negative. Blood chemistry, urinalysis, renal function tests, and agglutinations for typhoid, paratyphoid, undulant fever, and tularemia were all negative. Electrocardiogram was within normal limits. Two separate courses of sulfapyridine were given with no apparent effect on the temperature or the course of the disease. He received 410 grains in all. Following the second course, he developed an exfoliative dermatitis which we attributed to the drug. The highest temperature was 103.8 F. The fall was by lysis and did not become flat until the fifty-eighth hospital day. He was discharged on the sixty-first day as improved. The pneumonia here was of the bronchopneumonic type.

From the Medical Department, Elizabeth General Hospital and Dispensary.

We are indebted to Dr. Emil Stein and Dr. Joseph J. Labow for the use of Cases 4 and 3 respectively.

potentiality of antibody production. However, it is well known that transmission of the disease from the first case to other members of the same household does not occur very frequently, in spite of the presence of presumably susceptible children. While my own experience in Berlin showed that the disease spreads to other members only in about 12 per cent of the affected families, the figures of Moldovan⁷⁴ in Rumania reveal a still lower percentage, i.e., 7 per cent. When, finally, consideration is given to the fact that diphtheria antitoxin has been found in horses and in some species of monkeys, here too increasing with age, the relatively simple assumption of a specific immunization arising through latent infections becomes less and less tenable. Our difficulties in providing a satisfactory explanation are further enhanced by haphazard occurrence of atypical strains, biologic transformation, and dissociation of the diphtheria bacillus which seem to occur with particular frequency in countries with a low diphtheria morbidity.

'ROUND AND 'ROUND

"To get his wealth
He spent his health,
And then mid night and morn
He turned around,

And spent his wealth
To get his health again."

—Quoted by President of Southern Medical
Auxiliary at Greenville, S C

TABLE 1—SHOWING AMOUNT OF SULFAPYRIDINE GIVEN, THE HIGHEST TEMPERATURE, THE DAY OF HOSPITALIZATION ON WHICH THE TEMPERATURE BECAME FLAT THE DAY OF THE DISEASE ON WHICH THE TEMPERATURE BECAME FLAT, AND THE FINAL OUTCOME

Case	Sulfapyridine, Grains	Highest Temperature	Hospital Day Temperature Flat	Day of Disease, Temperature Flat	Outcome
1	275	105	27th	33rd	Improved
2	410	103 8	58th	79th	Improved
3	365	105 4	23rd	25th	Improved
4	75	106 4	Never	Never	Expired
5	220	103 2	6th	16th	Signed release
6	None	102	20th	22nd	Improved
7	1,140	105	Never	Never	Expired
8	584	103	15th	25th	Improved

plained of headache, generalized aches and pains, and anorexia ten days prior to admission. Seven days before admission he had a temperature of 104 F and complained of chilliness. Three days before admission he had pain in the right lower part of his back, and he coughed up blood-tinged sputum. When hospitalized the patient exhibited classic signs of consolidation of the entire lower two-thirds of the right lung posteriorly. The white count on admission was moderately elevated, and the red count was within normal limits. The Neufeld reaction for all available groups was negative. Sputum culture revealed *Str viridans*. Blood cultures were negative, as was the urine except for occasional traces of albumin. X-ray showed pneumonic consolidation of the middle and lower lobes of the right lung. Temperature on admission was 102.4 F. It came down gradually and was flat on the fifteenth day. He was discharged as improved.

Comment

In reviewing the clinical behavior of the cases, one notes that in 6 the physical findings were those of lobar pneumonia and that in 2 the findings were of the bronchopneumonic type. However, in none of the cases was there a crisis. The temperature in the recovered cases came down slowly by lysis except in 1, Case 5, where the temperature became flat on the sixth day of hospitalization and the sixteenth day of the disease (Table 1). This patient signed her release on the twenty-second day of hospitalization at which time, although there was marked clinical improvement, the pneumonic signs in the chest persisted. Of interest in this case also is the fact that it was the only one in the series which showed an organism on culture other than the *Str viridans*. Here the sputum culture showed both *Str viridans* and *Str hemolyticus*. The sputum cultures in all the other cases showed a florid growth of *Str viridans* only. Blood cultures in all of the cases were negative. The only complication due to the disease was observed in 1 of the 2 deaths of the series. In Case 7 there developed a small pleural effusion which on

culture revealed *Str viridans* and also a pericarditis just prior to death on the fifty-first day of hospitalization. In all she received 1,140 grains of sulfapyridine. The other death, Case 4, had been ill for two days prior to hospitalization and died twenty-four hours after admission. He had received 75 grains of sulfapyridine in all. Both of these cases were of the lobar type.

From this small series of cases it seems that the *Str viridans* does not produce a definite clinical picture in lung infections, however, it should be suspected in all cases of atypical pneumonia.

As to the value of sulfapyridine in these cases, all we are in a position to say from our very small series is that the response to the drug was not the definitely gratifying response we got in the pneumococcal pneumonias. Calmels,¹ before the advent of sulfapyridine, reported 2 deaths in a series of 11 *Str viridans* lung infections. In our series of 7 cases in which sulfapyridine was used there were 2 deaths, 1 occurring within twenty-four hours after admission to the hospital.

Conclusions

1 Eight cases of *Str viridans* pneumonia are reported, 2 of which expired.

2 Sulfapyridine was given in 7 of the 8 cases, including the 2 which expired. It did not produce the dramatic drop in temperature which we observed in our pneumococcal pneumonias, nor did it seem to alter the clinical course of the disease.

3 In all the cases the temperature came down by lysis, and the time required for the temperature to become flat varied from sixteen to seventy-nine days.

Case 3—W A, a white boy, aged 13, first became ill with a cold two weeks prior to admission. Two days before hospitalization, the patient complained of severe pain in the left chest and began coughing up rusty sputum. Physical examination on admission revealed a pleuritic rub at the left base posteriorly with bronchial breathing in the axilla and coarse rales. There were moist rales throughout the right side of the chest. The white count on admission showed a marked elevation. The red count was within normal limits. The Neufeld reaction with all available groups was negative. Blood culture was negative. Sputum culture showed a florid growth of *Str viridans*. Urine was negative, and x-ray showed a pneumonic process at the left base. Temperature on admission was 104.8 F. Three hundred and sixty-five grains of sulfapyridine were given during the first eight days of the illness and was discontinued when the temperature was 100 F. The temperature became flat on the twenty-third hospital day, and the patient was discharged on the twenty-fifth day as improved. The pneumonia was of the lobar type.

Case 4—M L, a white boy, aged 19, first became ill two days prior to admission when he complained of indefinite malaise, headache, and slight nausea. The following day he vomited on numerous occasions and began to expectorate yellowish sputum at first and then rusty sputum. On deep inspiration there was pain at the left base. Upon admission the patient was extremely toxic with signs of consolidation at the right base. The white count was markedly elevated, and the red count showed a mild secondary anemia. The Neufeld reaction with all available groups was negative. Sputum cultures showed a florid growth of *Str viridans*. Blood culture was negative. Lung aspiration was reported as *Staphylococcus aureus* and thought to be due to contamination. Temperature on admission was 102.8 F. The patient expired the following day. In all he received 75 grains of sulfapyridine. The pneumonia was lobar in type.

Case 5—E H, a white woman, aged 54, first became ill ten days prior to admission. At that time she complained of a cough and sore throat. Her condition gradually became worse, with fever and dyspnea. Just prior to admission she complained of pain in the left side of the chest. Physical examination revealed dullness of the left base posteriorly, with bronchial breathing and tactile fremitus. The white blood count showed a moderate elevation, and the red count was within normal limits. There was no Neufeld reaction with all available groups. The sputum culture showed a mixed growth of *Str hemolyticus* and *Str viridans*. The urine showed occasional traces of albumin. X-ray of the chest revealed infiltration of the base of the lung. The temperature on admission was 103.2 F and dropped in twenty-four hours to

100 F, where it remained for six days and then became flat. In spite of subjective improvement the signs persisted in the chest until the twenty-second hospital day, at which time she signed her release against our advice. She received in all 220 grains of sulfapyridine. The pneumonia was of the lobar type.

Case 6—S L, a white man, aged 51, first became ill two days prior to admission, with pain in the left side of the chest, cough, and expectoration of thick greenish sputum. The patient, suffering from chronic alcoholism, was intoxicated the day before he became ill and fell, striking the left side of his chest. On admission physical signs revealed coarse and fine crackling rales throughout both bases, decreased breath sounds, and slight impairment to percussion over these areas. There was also patchy distribution of increased vocal fremitus. The white blood count was moderately elevated, and the red count was within normal limits. The Neufeld reaction with all available groups was negative. Sputum culture showed *Str viridans*. Urinalysis was negative. X-ray of the chest showed congestion about both roots with infiltration of the lower lobe of the right lung. His temperature on admission was 102 F and dropped to 100 F on the next day. It remained so until the twentieth hospital day. He was discharged as improved on the twenty-third day. This patient did not receive any sulfapyridine. The pneumonia was bronchopneumonic in type.

Case 7—V C, a white girl, aged 18, complained of not feeling well a few days prior to admission. On the day of admission she complained of sore throat, cough, malaise, and pain in the right side of the chest. Physical examination at this time revealed very few signs in the lungs. On the following day there was diminished breathing at the right base with slightly increased vocal fremitus. On the third day there were frank pneumonic signs at the right base. The white blood count was moderately elevated, and the red count was within normal limits. The Neufeld reaction was negative with all available groups. Sputum cultures revealed *Str viridans*. There were no tuberculous bacilli found on sputum smears. Blood cultures were negative. Urinalyses were negative except for occasional traces of albumin. The first x-ray of the chest revealed a pneumonic involvement of the lower lobe of the right lung. Subsequent films showed a probable collection of a small amount of fluid in the right lung. Culture of fluid obtained by thoracentesis revealed a florid growth of *Str viridans*. The temperature on admission was 102 F, went up to 105 F, and then became a spiked one. She had five transfusions. In all she received 1,140 grains of sulfapyridine. She expired on the forty-ninth day, at which time a loud pericardial rub was heard. The pneumonia was of the lobar type.

Case 8—L H, a white man, aged 26, com-

venously, without apparent interference with urinary drainage, although the autopsy showed that both pelves and all calices were filled with mushy, gritty acetylsulfapyridine concretions. The patient, until death, passed large amounts of urine which reached as much as 44 ounces in twenty-four hours. She had, however, a continuous marked hematuria. The case was that of subacute bacterial endocarditis, and it was thought that the hematuria was due to a renal infarct. The absence of renal enlargement and hydronephrosis on autopsy pointed to the fact that the patient's ureters, which were found to be somewhat dilated, were particularly patent.

Other clinical manifestations are those of ureteral obstruction and may vary from slight unilateral or bilateral costovertebral pain to a typical colic with all its accompanying symptoms such as nausea, vomiting, and general prostration. In the latter the retention of urine above the site of ureteral obstruction is, as a rule, complete. It must be remembered, however, that complete retention may be associated with little or no pain at all. This has been the observation of one of us (R. L. D.) in a large series of ureteral calculi. In the case reported here the pain was more predominant on the right side, although the obstruction was more marked on the left side.

Oliguria undoubtedly indicates an incomplete bilateral obstruction and should call for cystoscopic drainage when it becomes evident that it cannot be relieved by administration of large amounts of fluid by mouth and intravenous injections of dextrose. Oliguria, as a rule, precedes anuria which ensues when both ureters become completely occluded. The recognition of the mechanical nature of this condition is extremely important, as timely cystoscopic intervention may be a lifesaving procedure. In a case reported by Tsao,⁸ death occurred in an 8-year-old child from marked oliguria following sulfapyridine administration. The autopsy showed complete obstruction of both ureteral orifices with sandlike material. The patient had hematuria and passed only 80 cc of urine during the week prior to death, the symptoms being attributed to hemorrhagic glomerulonephritis or chemical nephrosis. Tsao states "Had we had the knowledge and suspicion when the patient began to suffer anuria and tried cystoscopic manipulation of the ureter or even emergency nephrostomy, the life of the patient may very well have been saved." Carroll,⁹ on the other hand, in a more recent

report cites a case of complete anuria due to bilateral ureteral obstruction which followed the use of sulfapyridine in which he was able to re-establish kidney drainage by ureteral catheterization. In his case (a man, aged 42, who was treated for pneumonia), cystoscopy revealed a protruding concretion from the left ureteral orifice and a gritty sensation on passing catheters into both ureters. The patient made immediate clinical improvement, and the urinary output returned to normal following cystoscopy.

It is possible that anuria may be produced by massive deposition of crystals in the collecting tubules, and in such an event cystoscopic intervention obviously could not bring about the re-establishment of renal drainage. In one of the 4 cases of anuria reported by Brown and his co-workers,⁵ the patient died and the autopsy showed deposition of acetylsulfapyridine crystals in the collecting tubules. The authors do not state, however, whether any search was made for impacted concretions in the ureters, especially in their intramural portions.

Acetylsulfapyridine concretions are non-opaque to x-rays, but filling defects in the ureteropelvic tracts either on instrumental or intravenous pyelograms may indicate their presence. The intravenous pyelography may often be inconclusive, as the dye may not be visualized in cases of acute retention on account of temporary renal suppression, the ureters even under normal conditions are frequently not outlined.

Case Report

L. B., a white man, aged 71, night watchman by occupation, was seen on May 8, 1940. Previous history was irrelevant. He was particularly free from any symptoms of bladder retention. The onset of his present illness was sudden, with severe pain in lower right side of the chest aggravated on deep inspiration, cough, expectoration of greenish sputum, and fever (104.6 F). On examination, dullness, tubular breathing, and some leathery rales were elicited over the lower right side of the chest anteriorly and posteriorly. The pulse was 90 and respiration 34. Sputum examination by the Department of Health revealed type III pneumococcus. The patient received 70 grains of sulfapyridine for the first twenty-four hours and 20 grains more during the following day. The temperature began to drop and his respiration was much improved. On May 11 the patient began to complain of severe pain in the lower right side of the chest, and, because of a friction rub, it was thought to be due to pleuritic involvement. On the following day the patient was relieved of pain but developed an abdominal

ANURIA DUE TO COMPLETE BILATERAL URETERAL IMPACTION WITH CONCRETIONS FOLLOWING THE USE OF SULFAPYRIDINE IN PNEUMONIA

RALPH L. DOURMASHKIN, M D , and MORRIS WORTON, M D , New York City

THAT sulfapyridine has a marked tendency to crystallize within the upper urinary tract and form concretions has definitely been established both by animal experimentation and clinical reports. Antopol and Robinson¹ found urolith formation in the urinary tract of 24 out of 25 monkeys that were fed on sulfapyridine and had similar results in a series of 150 rats and rabbits with larger doses. Their work showed that the histology and gross pathology depends upon the degree of urinary stasis, and their findings were those of calculous ureteritis, pyelitis, and pyelonephritis in advanced cases. Simultaneously, Gross, Cooper, and Lewis² reported similar findings. Mollitor and Robinson³ found the concretions to be an acetyl derivative of the drug. This acetylation or conjugation probably represents an attempt on the part of the liver to detoxicate it. Marshall⁴ states that this detoxification is a failure, and he bases his belief on an experiment in which 7 out of 8 dogs died within forty-eight hours after an intravenous injection of sodium acetylsulfapyridine. Since all of his dogs showed, on necropsy, crystalline deposits in the collecting tubules and stones in the urinary tract, findings which were confirmed in reported autopsies of human cases, we are in complete agreement with Brown, Thornton, and Wilson⁵ that death resulted from interference with renal drainage rather than actual tissue damage due to toxicity of the drug.

Clinically, Brown and his co-workers⁵ reported a carefully selected and controlled series of 100 cases (of which 94 were pneumonias) in which sulfapyridine was administered. Twenty-six patients in this series developed urinary tract symptoms such as oliguria, anuria, and hematuria. Because of the marked tendency of the conjugated sulfapyridine to form urinary concretions due to its great insolubility, they advocate forcing of fluids and administration of intravenous injections of hypertonic solution of dextrose to prevent supersaturation of urine in cases showing diminution of urinary output and increase of the total and free sulfapyridine concentration in blood.

According to Long and Wood,⁶ crystalline deposits of acetylsulfapyridine are found in

the urine of all patients receiving the drug, so that their presence is of no great clinical importance. This observation was corroborated by Brown and his associates.⁵ A marked increase in the crystal content of the urine indicates rapid conjugation of the drug, and patients with this finding should be carefully watched.

It would seem to us that the symptoms of bladder irritability and the presence of hematuria are concomitant manifestations of "sand" in the urinary tract analogous to uric acid gravel or well-formed calculi of any other commonly known chemical composition. The experimental and clinical data accumulated in the literature within the period of a little more than a year and the study of our own case point definitely to the fact that hematuria is not a manifestation of toxic nephritis induced by the drug but is the result of local tissue laceration and that it may originate anywhere in the urinary tract.

The acetylsulfapyridine crystals are precipitated from both acid and alkaline urines, and according to Brown⁵ the rate of precipitation cannot be altered by administration of alkalis. In our case the pH of right and left urine was 7.5.

Leaving aside such theoretic considerations as the rapidity with which the drug is conjugated, its dosage is an important factor in causation of acetylsulfapyridine uroliths. However, the degree of urinary stasis may greatly depend upon purely local ability of the urinary tract to get rid of accumulated concretions. In Brown's⁵ series 22 out of 60 patients who received more than 25 Gm of the drug developed urinary symptoms, which included all of the 4 cases of anuria, while only 4 patients in 40 showed any evidence of urinary tract disturbance when the dosage of the drug was less than 25 Gm. However, in our case of a complete anuria found on cystoscopic investigation to be due to plugging of both ureters with concretions, only 6.5 Gm of the drug had been administered over a period of two days. On the other hand, in the remarkable case cited by Schiffrin,⁷ the patient received as much as 246 Gm of the drug over a period of sixty-three days, 81 Gm of which were given intra-

prove rapidly. The catheters were washed whenever drainage slowed up to insure against the clogging of their lumens. On removal of catheters considerable grating was elicited only on the left side. Thereafter his urinary output became normal and he was discharged from the hospital on May 19.

Summary and Conclusions

1. Animal experiments and clinical reports show definitely that sulfapyridine has a marked tendency to crystallize within the urinary tract with formation of acetylsulfapyridine concretions.

2. The recognition of mechanical nature of the interference with urinary drainage in cases of oliguria of complete anuria following the use of the drug is extremely important. Timely ureteral catheter drainage through the cystoscope may be a lifesaving procedure.

3. Hematuria should not be regarded as a manifestation of toxic nephritis induced by the drug. It is due to local tissue laceration and may originate anywhere in the urinary tract.

4. Even a small dosage of sulfapyridine may give rise to complete bilateral obstruction with anuria if local urinary tract conditions favor the retention of crystalline deposits.

5. A case is reported in which anuria resulted from complete plugging of both ureters with concretions following administration of only 6.5 Gm of sulfapyridine for pneumonia. Bilateral ureteral catheterization brought about re-establishment of kidney drainage and complete recovery of the patient.

PHYSICAL EXAMINATION OF ARMY RECRUITS

The physical selection and care of the army, a task which always necessitates the most exacting and unremitting work on the part of highly trained men, in time of emergency requires even greater organization and teamwork. Dr. George A. Skinner, Berkeley, California, points out in the October issue of *Hygeia, the Health Magazine*:

"It is still necessary," he declares, "to have an army largely composed of carefully selected, physically fit youth, if it is to operate successfully under all conditions, particularly the unexpected ones that always develop in actual combat." The substitution of older men or of those who are partially incapacitated physically, he says, will not work because such men rapidly break down under stress, requiring at least one man and often two or three to care for each disabled individual. Men who have passed the entrance examination generally resist most of the usual causes of disability.

The examination usually begins by putting the candidates through various exercises to determine whether all joints are normal. "The general examination for hernia, hemorrhoids, condition of the feet, skin and glands may then be made," Dr. Skinner says. "The eyes, ears, nose, throat, teeth, heart, lungs and nervous system are examined individually by specialists in these fields."

"At each point the printed physical examination form which the man keeps with him during the examination is taken by an attendant and a record of observations is made. At any point in the examination, if a question arises, the candidate is referred to a board of specialists for further examination. When all the findings are approximately normal, military clothing is provided for the individual. For this he is

carefully measured, particularly his feet. He is required to stand on each foot while a load approximating his pack is placed on his back. The shoes he is given are larger than those he has been accustomed to wearing, but after he has marched during physical training exercises, he soon realizes the comfort of these more roomy shoes.

"New men are vaccinated as soon as possible against smallpox and typhoid fever. Tetanus (lockjaw) preventive may also be added."

"Military training starts at once and the men are gradually accustomed to physical exercise. Many minor defects exist among accepted men and these are listed for correction by the medical department as rapidly as possible. Personal cleanliness and the care of the feet and teeth must be part of every soldier's training."

"The food supply of the army is most important. One of the duties of the medical department is to inspect food, not only before it is prepared but during the preparation and serving."

"With every group of men, contagious diseases soon appear. This is so predictable that it is often customary to isolate all new arrivals at training centers until a reasonable quarantine period has passed. With the first appearance of symptoms of a contagious disease, the suspect is at once removed to the hospital for further observation."

"It is not easy to keep an army physically fit, but it can be done to an extent that would have been unbelievable to army leaders two generations ago. Disease is now expected to cause less disability than injuries, but this has only been accomplished within the last half century. Previously battle injuries were far less than the disabilities caused by sickness."

distention. He did not void for twenty-four hours, and on catheterization 30 cc of blood-tinged urine was obtained. He developed twitching of the facial muscles and became quite drowsy. The temperature, pulse, and respiration were normal. He vomited on several occasions. On May 13, he continued to be drowsy, vomited several times, and toward evening became very toxic. He failed to pass any urine, and catheterization yielded 45 cc of dark brown urine. On May 14, he continued to be anuric and abdominal distention recurred. The tongue was moist, which indicated that the anuria was probably not due to renal suppression. The chest showed signs of pneumonic resolution on the right side. Considerable tenderness was elicited over the right costovertebral angle, while the left side was but slightly tender. No flatness was elicited over the bladder region, and on catheterization but a few drops of dark bloody urine were obtained. The patient had now been anuric for nearly three days.

Toward evening the patient was removed to Manhattan General Hospital in an ambulance which traveled a distance of nearly 220 city blocks.* Four and one-half hours after catheterization, before anything else was done for the patient, he voided 7½ ounces of bloody urine. He became very much brighter, and within the next nine hours he passed 59 ounces of urine. On the following morning he suddenly began to complain of severe pain in the right costovertebral angle and developed an abdominal distention. He became completely anuric for the next twenty-eight hours, although he had received two intravenous injections of 50 cc of 50 per cent dextrose solution and 2,370 cc of fluids by mouth. The abdominal distention and drowsiness returned. The blood count showed 80 per cent hemoglobin, 4,400,000 red blood cells, 14,000 white blood cells, of which 84 per cent were polymorphonuclears with 72 per cent segmented cells. The blood chemistry revealed 90.9 mg of glucose, 2.8 mg of creatinine, and 64.2 mg of nonprotein nitrogen per hundred cubic centimeters. The urine voided on the previous day had a specific gravity of 1.015, was alkaline in reaction, had a trace of albumin, and contained numerous red blood cells but no pus cells. The blood pressure was 150 systolic and 90 diastolic. The x-ray showed moderate lateral curvature of the spine but no evidence of calculi in the urinary tract. The silhouettes of both kidneys, because of excessive presence of gas in the intestinal tract, could not be made out.

Cystoscopic examination on May 16, twenty-eight hours after the last passage of urine, revealed the following. Not a drop of urine was obtained through the sheath of the cystoscope.

* On numerous occasions one of us (R. L. D.) has noted that a severe renal colic due to ureteral stone impaction may subside following a prolonged automobile ride. This is probably due to the fact that the shaking of the patient may cause a dislodgment of the calculus within a ureter, thus allowing the passage of retained urine.

The bladder mucosa was considerably reddened in the region of the trigon. There was no evidence of vesical neck obstruction which was in conformity with the previous rectal examination that showed no prostatic enlargement. The left ureteral mound was markedly reddened and edematous, and through a minute orifice a grayish white concretion was seen to protrude. The right orifice was also minute but otherwise looked normal. A number 6 Charrière catheter was introduced with difficulty into the left ureter for a distance of 3 cm, when suddenly long ureteral casts of sandlike material began to escape into the bladder alongside the catheter. The latter was slowly worked with to and fro motions into the ureter for another 5 or 6 cm., releasing more of the above casts which broke up into innumerable minute particles within the bladder. With continued difficulty the catheter was finally passed way up to the kidney pelvis, a gritty sensation being elicited. As the eyes of the catheter were undoubtedly clogged in their passage over the sandy impaction in the ureter, no urine was at first obtained, but, as soon as the patency of the catheter lumen was re-established by injection of a few cc of sterile water, clear urine began to drip in a rapid flow, indicating retention. On the right side a similar catheter was passed for a distance of 24 cm before a definite obstruction was encountered. This obstruction was passed by with difficulty. Here again the patency of the catheter lumen had to be restored before clear, watery urine began to escape in a rapid, almost continuous flow. Phenolsulfonphthalein, injected intravenously, appeared at the end of eight minutes in both urines in equal and fair concentration. The segregated specimens of urine showed a pH of 7.5 on both sides, urea—1.2 Gm per one cubic centimeter on the right side and 1 Gm per one cubic centimeter on the left side. The microscopic examination revealed a few red blood cells, but neither pus cells nor microorganisms were found. A few crystals of acetylsalicylpyridine were noted in both specimens, and on chemical examination only faint traces of the conjugated drug were found. This was undoubtedly due to the fact that at the time of the cystoscopic examination the patient had conjugated practically all of the drug which had precipitated in both ureters. The cultures showed no growths at the end of forty-eight hours. We were so absorbed in the effort to re-establish kidney drainage that, unfortunately, no attempt was made to recover the concretions that escaped from the left ureter into the bladder for a chemical and microscopic examination. Immediately after ureteral catheterization, pain in the right kidney disappeared. The catheters were allowed to remain indwelling in both ureters for twenty-four hours, and during this time 34 ounces of urine were obtained from the right kidney and 30 ounces from the left, in addition to a few ounces which he voided voluntarily. His general condition began to im-

gen and sugar were normal. Tests for bile pigments in the stool were positive. Brom-sulfalein test (2 mg per Kg) showed a 100 per cent retention at five minutes and a 50 per cent retention at thirty minutes. Blood Wassermann and Kahn tests were negative for syphilis. Roentgenologic examination of the long bones, skull, chest, and pelvis was normal. Visualization studies of the gall-bladder revealed a diminished concentration of dye. No biliary calculi were seen. Duodenal drainage was attempted but was unsuccessful probably because of marked pylorospasm. Further attempts at drainage were refused. Patient was given symptomatic treatment. Surgical intervention was advised but also refused by the patient, and she was discharged on the twenty-fourth day of hospitalization in an essentially unchanged condition.

During the next twenty-three months the patient was hospitalized on five different occasions. Her complaints on these admissions consisted of her usual symptoms which were nausea, right upper quadrant discomfort, dyspepsia, and persistent jaundice. Her stools during this period contained bile pigments. Her fourth admission was complicated by a lobar pneumonia which responded to sulfapyridine.

The findings on physical examination during these periods of hospitalization were essentially similar to those on admission.

During this period of observation much laboratory data were obtained. The serum van den Bergh varied between 2 and 9.5 mg of bilirubin per hundred cubic centimeters with a direct positive reaction. The icteric indices fluctuated between 34 and 53. Stool examinations showed only small amounts of urobilin. Blood cholesterol and cholesterol esters were consistently elevated, the level of the former averaging 480 and the latter 120 mg per hundred cubic centimeters with a ratio of 25 per cent. Numerous urine analyses showed a 4 plus foam test for bile. Hemoglobin remained at about 11.0 Gm per hundred cubic centimeters with a red cell count of 3,000,000 per cmm. A slight leukopenia was present during this period, the white cell count averaging 4,800 per cmm. The differential count was not remarkable except on one occasion when a 12 per cent eosinophilia was found. Examination of one of the orange-yellow plaques removed at biopsy was reported by the pathologist as "a cholesterol granuloma."

Final Admission—At this time the patient

was hospitalized because of drowsiness in addition to her usual complaints. During the interim of seven months between her fifth and final admission she also noted progressive increase in the size of her abdomen and slight ankle edema. There were periods during which she noted right upper quadrant pain associated with a spike in temperature usually lasting twenty-four hours. Physical examination revealed no pronounced change in the intensity of her icterus. The patient was semicomatose, rousing only to vigorous stimuli. The orange-yellow plaques of the skin previously noted were still present. The abdomen was moderately distended. There was shifting dullness in both flanks, and a fluid wave was easily elicited. Abdominal paracenteses were performed on two occasions with the release of 1,100 and 2,700 cc of a clear, amber fluid. Following the taps the liver edge could be palpated 10 cm below the costal margin. It was smooth, firm, and somewhat tender. The tap of the spleen was felt 8 cm. below the costal margin.

The patient's course in the hospital was one of gradual decline despite active therapy. Coma appeared on the tenth day and was associated with a sudden rise in temperature to 105 F (40.5 C). Exitus occurred on the same day.

Serum bilirubin during this period was 24 mg per hundred cubic centimeters. The icteric index had risen to 136. The total serum proteins were 6.7 Gm per hundred cubic centimeters consisting of 2.7 Gm of albumin and 4.0 Gm of globulin with an A/G ratio of 0.7. Blood cholesterol, which had been uniformly high previously, dropped to 205 mg per hundred cubic centimeters. The cholesterol esters were 35 mg per hundred cubic centimeters. Examination of the ascitic fluid revealed a specific gravity of 1.010, a total protein content of 1.4 Gm per hundred cubic centimeters and contained bile. Bacteriologic examination of the ascitic fluid was negative for *Bacillus tuberculosis* and bacterial growth. A cell count could not be done because of clotting, but the predominating cells were lymphocytes.

Discussion

DR. CARL H. GREENE. This is the case of a woman 43 years of age who came to the hospital because of recurrent attacks of jaundice which dated from her adolescence. The early history was rather uncertain, for at one time she said she had her first attack at the age of 17 and on another occasion she said it was at the

Diagnosis

THIS new JOURNAL section will carry case reports that have been made the subject of discussion from the point of view of the diagnostic process needed and the post-mortem evidence. All the cases will be selected because of some unusual interest. Two hospitals in this city have very kindly offered to supply this material, each six times a year. Reports from the New York Post-Graduate Hospital will alternate with reports from Bellevue Hospital, Fourth Medical Division. These reports form a companion piece to the Cornell Medical College Conferences on Therapeutics.—*Editor*

Date November 19, 1940
Presiding Dr Irving S Wright

History

DR ROBERT McGRATH This patient was treated in the dispensary and wards over a period of twenty-three months. During this time there were six hospital admissions.

First Admission—A 43-year-old, white American woman entered the hospital for the first time complaining of vomiting of one week's duration and of jaundice which had been present constantly for two years. She previously had jaundice for about one month sometime between 12 and 17 years of age but was unable to give further details concerning any associated symptoms. At the age of 29 she was told she had syphilis and was given about nine intravenous treatments of an unknown drug with no untoward reactions. After this time all serologic tests for syphilis were negative. At 30 years of age she had an attack of severe right upper quadrant pain with fever and jaundice which passed off in several days. At 37 she had a similar illness but had jaundice for six months. During this episode, she was admitted to Hospital A where operation was advised but refused. A letter from Hospital A gave the following significant data: icteric index 65, blood Wassermann negative, stools were light colored but not acholic, and x-ray examination of the chest and long bones was normal. No abdominal x-ray studies were made. When 41 years of age, the patient experienced a similar attack from which she never made a complete recovery. Her icterus persisted and deepened. There was a weight loss of 77 pounds over a period of one year, associated with asthenia and anorexia, her usual weight being 197 lbs. She also noted the development of "yellowish spots" in her skin located

particularly on the eyelids and fingers but to some extent over the entire body. At this time she entered Hospital B for observation where she was told that surgical intervention should not be done and was discharged in a relatively unchanged condition. Significant laboratory data obtained from this institution was the finding of an elevated icteric index and a blood cholesterol of 725 mg per hundred cubic centimeters.

Family history was of interest—her mother died at the age of 70 with jaundice of unknown origin and her father died of tuberculosis at 43.

Physical examination showed an emaciated woman whose skin was colored a peculiar dark grayish yellow. There were slightly elevated orange-yellow plaques in the skin of the eyelids, elbows, knees, and body. Examination of the neck, chest, and heart was normal. A small epigastric hernia was found. The liver edge was felt 10 cm below the costal margin. It was firm, nontender, and smooth. The lower margin of the spleen was palpated 3 cm below the costal margin. No other masses were felt.

Urinalysis showed a plus protein and a 4 plus foam test for bile. The hemoglobin was 11.0 Gm per hundred cubic centimeters with a red cell count of 3,200,000 per cubic millimeter. The reticulocyte count and fragility of the red blood cells were within normal limits. Platelets numbered 84,000 per cubic millimeter. The white cell count and differential were normal. Bleeding and clotting time were within the normal range. The serum van den Bergh was 8.8 mg of bilirubin per hundred cubic centimeters, with a direct, positive reaction. The icteric index was 83. The findings for blood cholesterol and cholesterol esters were 450 and 125 mg per hundred cubic centimeters, respectively, with a ratio of 37 per cent. Blood nonprotein nitro-

with obstructive jaundice due to constriction of the common duct whether inflammatory or neoplastic in origin. Montgomery believes that the etiology of neoplastic or systemic xanthomatosis remains to be determined and that no one theory satisfactorily explains all the different forms.

I am personally in accord with Montgomery's view. Many patients with cutaneous xanthomata show no change in the blood cholesterol levels. It has been recognized that increased blood cholesterol in diabetes mellitus may or may not be associated with an active lipemia and that there is no direct relationship between the level of the blood cholesterol and cutaneous xanthomatosis. The most striking illustrations of cutaneous xanthomatosis are seen in the medical textbooks of half a century ago. Such books as J. Wickham Legg's³ have illustrated examples of extensive cutaneous xanthomatosis associated with gallstones. It is my belief that the surgeons are the cause of the infrequency of these cases at the present time. The average patient with jaundice is operated on early, and so it is only occasionally (as in the present instance) that cases of long continued obstructive jaundice are seen. These latter are very apt to show hypercholesterolemia independent of the nature of the obstructive lesion.

The diagnosis in this patient would have been made more certain if it had been possible to do a satisfactory duodenal drainage in order to examine the bile for crystals and bacterial flora. In our experience the finding of *Bacillus coli* and of calcium bilirubinate crystals in the duodenal drainage is usually pathognomonic of stone in the common duct.⁴ Enlargement of the spleen is not commonly seen in the early stages of obstructive jaundice, but, when obstruction has lasted sufficiently long, the development of a secondary obstructive fibrosis occurs (obstructive biliary cirrhosis) and splenomegaly then develops.

My final clinical diagnosis is chronic cholecystitis with stones, probable stone in the common duct, obstructive biliary fibrosis with secondary congestive splenomegaly, generalized xanthomatosis, and hepatic insufficiency.

DR WRIGHT: Dr. Greene, do you believe that there is such a syndrome as primary xanthomatosis? If not, how do you explain

the small xanthomatous plaques frequently seen on the eyelids of patients with no evidence of biliary pathology? Should these plaques be considered a definite indication for a complete liver and gallbladder study when unaccompanied by other signs or symptoms?

DR GREENE: Yes. I do think that there is a syndrome as primary xanthomatosis. The mere presence of xanthomatous plaques is not adequate indication for a complete liver and gallbladder study. The patient should exhibit symptoms referable to these systems in order to warrant such an investigation.

Clinical Impressions

Primary disseminated xanthomatosis or chronic cholecystitis with cholelithiasis and obstruction to common bile duct with secondary xanthomatosis.

Biliary cirrhosis

Dr. Greene's Diagnosis

Chronic cholecystitis with stones

Probable common duct stone

Obstructive biliary fibrosis with secondary congestive splenomegaly

Generalized xanthomatosis

Hepatic insufficiency

Pathology

DR MAURICE N. RICHTER: The lesions of principal interest are in the biliary system. The liver is enlarged, weighing 2,000 Gm. It is deeply jaundiced and presents the picture of biliary cirrhosis. The gallbladder is contracted and scarred and communicates almost directly with the common bile duct. Nine calculi are found in the gallbladder. Although no stones are found in the common duct, obstruction has evidently been present, for the common and hepatic ducts are dilated and their mucosae are bile-stained.

The spleen weighs 925 Gm. and is soft and flabby.

Microscopically the liver lesion is that of biliary cirrhosis. Bile pigment is found in both liver and Kupfer cells, especially in the region of the efferent veins. A slight increase in number of bile ducts and an occasional vacuolated cell is noted in the portal areas. Practically no lipid is demonstrable with Sudan IV or osmic acid, and examination of frozen sections with polarized light shows no anisotropic material. No xanthomata are seen in the liver or in the extrahepatic bile ducts. The skin lesions, however, are typical xanthomata with cholesterol deposits.

The spleen shows moderate diffuse fibrosis,

³ Legg, J. Wickham. *On the Bile Jaundice and Biliary Diseases*. New York, Appleton and Company, 1880.

⁴ Carter, R. F., Greene, Carl H., and Twiss, J. R. *Diagnosis and Management of Diseases of the Biliary Tract*, Lea and Febiger Philadelphia, 1939.

age of 12. She had had four major attacks prior to her first admission to the New York Post-Graduate Hospital. Several of these were associated with fever and jaundice. These attacks were sufficiently severe so that a diagnosis of acute cholecystitis with stones was made at another hospital. Following the early attacks the jaundice cleared up, and she was well during the interval. The jaundice persisted for two years prior to her final admission to the hospital. After a year of jaundice she was studied in a third hospital when chemical studies showed a blood cholesterol of 725 mg per hundred cubic centimeters. This figure was outstanding since the normal blood cholesterol usually varies between 180 and 230 mg per hundred cubic centimeters. The highest blood cholesterol that has been found in the laboratories of the New York Post-Graduate Hospital is 2,100 mg per hundred cubic centimeters. This was in a patient who had an acute pancreatitis, diabetes mellitus, and xanthomatosis. In the present patient the reading of the blood cholesterol, therefore, is significant because of its elevation, but it is by no means exceptional.

The physical examination on admission revealed a large firm liver, a large spleen, and jaundice. The appearance of the skin was noteworthy, because in addition to the yellow color of jaundice she showed the generalized deposition of melanin pigment that is so often associated with long standing chronic jaundice. In her case the skin color seemed to be due to a combination of bilirubin and melanin (black jaundice) without any marked greenish component. This darkening of the skin further accentuated the striking appearance of the xanthomatous spots around the eyes, fingers, knees, and other places on the body.

Because of the history of recurrent attacks of upper abdominal colic associated with fever and jaundice, a preliminary diagnosis of chronic cholecystitis with stone and a probable stone in the common duct was made. Operation was advised but refused by the patient.

Other causes of jaundice were taken into consideration in the differential diagnosis. Because of the early age of onset (12 years?), the large spleen, and the history of jaundice in the mother at the time of her death, familial hemolytic jaundice was considered. It was felt, however, that this could be eliminated completely. In the first place the development of jaundice in the mother at the age of 70 was a strong argument against the familial

type. This patient's freedom from jaundice during early childhood, the normal character of the erythrocytes, and the absence of reticulocytosis and spherocytosis would seem to exclude hemolytic jaundice, although it must be recognized that a considerable proportion of patients with congenital hemolytic jaundice develop gallstones. When a patient has obstructive jaundice superimposed on a hemolytic jaundice the laboratory findings cease to be characteristic of the latter.

Biliary cirrhosis or chronic hepatitis was considered in the differential diagnosis, particularly in view of the story of antisyphilitic treatment at 29 years of age. This was discounted because of the first attack of jaundice possibly antedating puberty, and there was no history of continued exposure to alcohol or other hepatotoxic material. It is not unusual for a case of cirrhosis to have such a prolonged history with recurring exacerbations such as was reported in this case.

When this patient was first admitted to the New York Post-Graduate Hospital she was demonstrated before the medical conference as a possible case of generalized xanthomatosis with associated biliary cirrhosis of the type described by Thannhauser and Magendantz.¹ In their article Thannhauser and Magendantz describe in detail the various clinical pictures presented by disturbances in function of the reticulo-endothelial system such as Gaucher's disease with the deposition of sphingomyelin in the foam cells of the reticulo-endothelial system. These authors explain xanthomatosis on the basis of the active production of various lipoids in foci of xanthoma cells in the body. Thus, the condition of systemic xanthomatosis can be looked on as a primary disturbance of lipid metabolism. It is further explained that biliary cirrhosis is secondary to destruction of the finer radicals of the bile ducts by deposits of cholesterol in their walls. These latter are similar to the deposits of cholesterol in the wall of the gall bladder in cases of cholesterosis or so-called "strawberry gallbladder." This view of Thannhauser and Magendantz has not been generally accepted, and Montgomery² takes exception to the view that generalized xanthomatosis represents a primary disturbance in cholesterol metabolism. He agrees that xanthomatosis is sometimes seen in association with hepatic disease, but he points out that this is particularly so in association of cases

Special Article

A STUDY OF COUNTY SOCIETY ACTIVITIES

JOSEPH S. LAWRENCE, M.D., Albany, New York

THE County Medical Society is the unit of organized medicine. This being true, it is most desirable that the members of such society should realize the necessity of keeping it a strong, active component of the larger state organization.

In New York State there is an active society in every county but one. That county is Hamilton, in the Adirondack Mountains, and its limited population is located in a few small centers or near to its boundary so that adequate medical care is provided by a few resident physicians (too few to organize a society), and others residing near the border of neighboring counties.

The sixty-one county societies range in membership from eleven physicians in Schuylar County to approximately five thousand in New York County. Twenty-four societies have fifty or fewer members and another eighteen range between fifty-one and one hundred. Three have more than one thousand members. In some of the rural counties 100 per cent of the physicians are members of the society, while in some of the densely populated counties the proportion of members is as low as 60 per cent. Physicians locating in rural counties usually seek membership in the county society as early as possible after registration of their licenses and location of offices. Membership is sought not only for scientific advantages and fraternal associations but to establish a reputation for merit and regularity and also to benefit from the protection the society provides against charges of malpractice.

A society's efficiency will depend, in part at least, upon the number of times it convenes. When the prime objective of a meeting of the society was to hear a scientific address and join in the discussion, it was no serious matter if the meetings were not held regularly or if the interim between meetings was great, but today the society has important business obligations and must, therefore, meet frequently and regularly. If the secretary of a society that meets but twice a year receives a letter shortly after the meeting, he will not be able to get the society's consideration of it for six months, and

by that time action may be too late. Eleven societies have but two regular meetings annually, another twenty-two meet four times a year. Twenty-one meet eight or more times, two of these meet monthly throughout the year. It would seem that all societies should try to meet at least six times a year for the purpose of transacting business. Of course, if there is exceedingly urgent business to be transacted, a special meeting is called. Some societies hold a short business session in connection with the lectures when they are having one of the postgraduate courses, others may have a majority of members on the staff of a certain hospital and take advantage of a clinical conference day to have a special meeting. Too few take as seriously as it deserves the business part of their meetings, i.e., the consideration of communications, of committee reports, and of the reports of their delegates to meetings or committee conferences of the State Society. Some of the societies endeavor to transact their business in the half hour before the time set for the scientific session, and, if a quorum does not arrive or there is too much business for that time, the meeting is adjourned until after the scientific session closes, when another desperate effort is made to secure a quorum. Of course, where the county society has a *comitia minora* authorized to do certain business, there is need only for the acceptance of its report with the transaction of such business as it requests in the general business meeting.

In recent years societies are devoting more time to the discussion of problems arising out of changing social conditions. Occasionally, a society will devote an entire meeting to a discussion of problems incident to medical care of indigent sick, practice under the Workmen's Compensation Law, or medical preparedness.

Most societies do not have established headquarters where mail can be received and records kept. The only permanent records preserved under such conditions are the secretary's minute book and the treasurer's receipt book. The places where meetings are usually held are club houses, hotels, and

presumably from portal congestion. This picture is modified by an acute splenic tumor and by the presence of occasional foci of developing blood cells. No "xanthoma cells" are seen.

It is our interpretation that these findings indicate biliary cirrhosis from common duct obstruction and that this obstruction was due to calculi and not to xanthomata in the biliary system. On this basis the hypercholesterolemia and the xanthomata in the skin are the result, rather than the cause, of the obstructive lesion.

DR WRIGHT: I should like to ask Dr Richter whether he thinks there is such a thing as biliary cirrhosis due to obstruction by xanthomata in the bile ducts.

DR RICHTER: I have not seen it. In the present instance this was not the case.

Pathological Diagnosis

Chronic cholecystitis

A LEGAL KINK IN MEDICAL CARE FOR REFUGEE CHILDREN

A physician in an Ohio community was called to attend a small child who had been brought to this country from England for placement in an American home to escape the dangers of war, and, as reported in the *J. A. M. A.*, he found that the child was suffering from badly diseased tonsils and adenoids. He recommended an operation but was advised that the surgical procedures contemplated could not be undertaken lawfully until consent was obtained from the child's parents in England. As more and more European children are placed in American homes the problem that confronted this physician will necessarily constantly recur. Any unnecessary delay in providing medical care for the children would be most unfortunate. The United States Committee for the Care of European Children, in which now centers the responsibility of securing American homes for the young refugees, has given this matter of authorization of medical care considerable thought. The committee realizes the importance of the matter and is working on a plan to effect a definite solution to the problem. Pending the completion of this plan, however, the committee thus expresses the view that there need not now be any such delay as was suggested to the Ohio physician.

"Pending a more permanent arrangement, the United States Committee and any foster parents, however, are not left completely remediless. We feel that there is a degree of factual background which would enable a foster parent, on

the basis of general American law, to consider himself as acting in loco parentis. Among such factors are that the English parents of their own volition sent their child to an American home and assumed all the risks inherent therein, that the American foster parents have taken the child into their home, have supported it, have cared for it, and generally have exercised custodial powers over it. Certainly, it would seem such foster parents could exercise their rights over the child as against any other individuals, with the exception of the child's actual parents. Bearing such factors in mind it would appear likely that American courts would hold that the American foster parent, having assumed all these rights, duties, and obligations, would likewise have the power to consent to any necessary medical or surgical treatment of the child.

"We feel that there are also two further mitigating circumstances. In the first place it is highly unlikely that the question would ever be raised except by the English parents themselves and it is extremely doubtful, in view of all the circumstances, that they would complain. In the second place, we feel that an American court would be reluctant to hold the United States Committee or the foster parents liable for such a given consent when the whole picture of this emergency child care movement was adequately and forcefully presented. If, on the other hand, the foster parents were negligent in handling the matter they should be held liable."

SIGHT FOR SORE EYES

A number of years ago an elderly colored woman presented herself at my clinic with a cataract, relates an Iowa doctor in *Modern Medicine*. I operated and after about ten days she was ready to go home. I decided I would see how much vision the old lady had, following the removal of the cataract. I put a trial frame with some lenses in my pocket and went to the hospital. I said to my nurse, "Come with me and we will see how much vision our patient has."

We went to the ward and the nurse removed the bandage while I slipped the trial frame in place and dropped in the lenses that would give her approximate correction. I said, "Now, Auntie, what can you see?"

She twisted her head around until she got the proper focus and then said, "Well, doctah, I sees that you ah a pow'ful han'som man." The nurse took all the joy out of the remark by saying, "She can see better than I can."

Expenditures

One and only one item of expense is common to all societies and that is the cost of preparing and mailing notices of the meetings. The next most common expense is for secretarial and stenographic services. It is often said that an organization will be active or lethargic depending upon the interest of its secretary. There is much reason to believe that the saying holds true with medical societies. Secretaries usually take great pride in their duties and submit to re-election so long as their health permits them to do the work. Several have served more than fifty years. Many of those with long years of service have never received anything for their loyalty but a vote of thanks. Seventeen societies do not compensate their secretaries in a material way, twelve allow them amounts ranging from an uncertain sum to \$100 for the payment of necessary clerical assistance. Six remit the dues of their secretaries, fourteen grant an honorarium of \$10 to \$50 annually, and seven others grant amounts varying from \$100 to \$250.

Four societies that do not compensate their elected secretaries employ executive secretaries to be their assistants and to devote their whole time to the work. One society employs its elected secretary as its executive secretary on part time.

This study has convinced the writer that the time has come when a society secretary must be able and willing to devote more than a few spare minutes to his duties if the society is to retain its importance and live up to its responsibilities as a component of a large, influential State Society. A busy practitioner should not be expected to do this work without some compensation for the time and service he must provide. Obviously not all societies can afford nor will their needs require the full time of an executive secretary, but all societies, no matter how small, will and do require an increasing amount of time of one of their members to keep the minutes of the meetings and the records, to supervise matters relating to workmen's compensation, to coordinate the duties and stimulate the activities of the several committees, to arrange for postgraduate education, and in many ways to represent his society with local, state, and national organizations.

The secretary continuing in service from administration to administration becomes known as the representative of the society through whom all inquiries or suggestions for

society activity will pass. Of course, the society has committees appointed to function for it in their respective fields, but often the secretary must function for them. In twenty-six counties the secretary serves as treasurer also, and seven of these secretaries are among those receiving no financial assistance from their societies.

The treasurer is another officer who is re-elected as often as he consents to accept the honor. In twenty-six societies, as was stated before, the secretary functions also as the treasurer. Only ten of the other thirty-five treasurers receive compensation, two, an uncertain honorarium, two, remission of dues, four, \$50, one, \$100, and another, \$300.

Delegates to State Society

Twenty-four societies refund in full to their delegates to the meeting of the House of Delegates the actual expenses incurred in making the trip. Of the others, one society refunds \$15 to each delegate, while five others refund up to \$25 and one to \$35. One society refunds the railroad fare and compensates each delegate \$10 per day. Five refund the railroad fare only, while four refund railroad fare and hotel expenses. Twenty require that the delegate meet all of his expenses himself. They feel that a member should be willing to make that contribution for the honor of representing his society. Sometimes members refuse the honor and representation depends upon the willingness of a member expecting to attend the scientific meeting to be the delegate.

The meeting of the House of Delegates is the most important affair in the annual experience of the State Society, and every county society should be keenly interested in its transactions and, therefore, have able representation. A delegate should be familiar with the State Society's program and be prepared to give the meeting the benefit of his county society's attitude or experience.

Honoraria

Inquiry was made regarding compensation of guest speakers at county society meetings. More than half (thirty-seven societies) replied that they offer to repay their expenses or make them an honorarium. Twenty replied that it is not their practice to do anything, and four others said they do so occasionally. A few years ago large clinics and hospitals would meet the expenses of members of their staffs who accepted invitations to take

hospitals At least five societies (Erie, Kings, Monroe, New York, and Queens) have offices and facilities for holding their meetings in the same buildings Where facilities for preserving records are inadequate, the responsibility for the continuance and efficiency of the society rests largely on the secretary He is elected for a term of one year, but almost without exception he will be re-elected annually as long as he will accept the honor and task The president is elected for a term of one year, also, but is rarely re-elected The treasurer and delegates to the House of Delegates of the State Society are usually re-elected in two or more years Where the society meets but twice a year, the president has very little opportunity to render much service He is elected in October, and unless he prepared himself in advance he will not be in a position to declare his program or appoint the chairmen to his committees at once He is likely to take his time, for the next meeting will not be until May Thus, the active part of his year may pass before he has completed his organization, and by that time vacations are at hand and society affairs are reduced to a minimum He will probably endeavor to have the coming October meeting worthwhile, but it will be unbecoming for him to prepare a program for further activity since his term of office expires Even where it is the custom to advance the vice-president, it is not likely to be different Officers should be chosen who are qualified and willing to contribute actively both in time and effort

Attendance of members at meetings is the bugbear of all active officers It is affected by many conditions and circumstances A good program, including a live subject or a prominent speaker and, better still, a combination of the two, usually results in a good attendance The weather, the place of meeting, and the hour, all influence the attendance In the rural districts the best attendance is secured when the meeting includes a meal For example, the business portion of the program may be held before luncheon and the scientific in the afternoon, or the program may be built in like manner about dinner in the evening In the cities, discontinuance of a collation after the evening meeting will be followed by a marked decrease in attendance

Attendance is not influenced greatly by the size of the membership unless the effect is in adverse ratio Rural county societies may have 80 or 90 per cent of their members in attendance, while the larger urban societies may have at times relatively small meetings

Many societies have one meeting a year which is principally a social affair It may be a clambake, a beefsteak supper, a summer outing, or a joint meeting with the lawyers, the dentists, or the auxiliary Such meetings are usually very worthwhile and well attended

The annual meeting when officers are elected is usually a dinner meeting among the smaller societies, and occasionally the members are invited to bring their wives A few societies divide their annual meeting into two parts—business on one evening and the banquet another evening

Incomes

Dues, exclusive of State Society dues, assessed annually by county societies vary in amount from \$1 00 to \$25 (see Appendix) Twenty county societies assess themselves \$2 00 annually, while twenty-two collect \$5 00 Four societies collect \$10, one, \$20, and three have sliding scales ranging from \$10 to \$25 in two societies and from \$12 50 to \$25 in the third In these three societies physicians who are just starting to practice are favored with the lower dues One society has no regular annual dues but assesses its members \$5 00 whenever it is necessary It reports that there has been one such assessment in the last four years Most societies have no other income than that received from dues There are, however, other sources—eight societies collect a fee for registering the members under the Workmen's Compensation Law, four collect dues from associate members, four have endowments or moneys at interest, three realize a profit on their bulletins, and two collect an initiation fee Other sources of income reported are use of society building by other groups, radio talks, refraction of eyes of children for city, clinics, and school health service

It is interesting to note that the county societies collect annually in dues, exclusive of the State Society assessment, a total of more than \$210,000 Only one society reported having an endowment It is the gift of a former member who was president of both the county society and State Society One wonders why more societies should not have endowments

One might speculate as to why there should be such a great difference in the amount of dues collected by the different societies It is evident that they collect dues in keeping with their activities

gathers the information for the bulletins. He also represents the profession at public hearings.

Copies of the printed bills discussed in the bulletins are sent to the chairmen of all county society legislative committees, and they are asked to give the State Committee the opinion of their committees at the earliest opportunity. In spite of the elaborate efforts made to secure expressions of opinions and with the assurance that these comments help the State Committee arrive at a decision as to whether a bill should be approved or opposed, the number of replies received is often disappointing.

About a month after the legislature has convened the chairmen of the county society legislative committees are invited to a conference in Albany, at which time the bills that have been introduced are carefully studied and discussed and a decision is reached upon each. These conferences are considered very worthwhile by the State Society and the chairmen who attend. Although the State Society refunds to each chairman the expenses incurred in attending the conference, only about one-half of the county societies have been represented at any particular conference. Of course, it is understood that all chairmen cannot leave their practice on a particular day—and for those farthest from Albany two days—but probably some chairmen do not take their responsibility as seriously as the position deserves. During 1940 we did not have a communication from thirteen of the sixty-one county chairmen nor from any member of their committees. There were eleven other county chairmen of committees from whom we did not hear, although some member of each of those committees did send us some comment. Only six of these twenty-four chairmen attended the annual conference. It is possible that some of these chairmen modestly thought that their comments were not needed, for we know that some of them did keep in close touch with their legislators. This seeming lack of cooperation was not always the fault of the chairmen, for to our knowledge some were not appointed or notified of their appointment until January. It is possible, also, that some chairmen hesitate to express an opinion that would be interpreted as the position of their societies without having instructions. They are unable to secure these instructions because their societies do not meet again until after the legislature has adjourned. These chairmen should consult with the other members of their

committees—a practice too frequently neglected.

Another important committee is the public health committee. Forty-eight societies have such a committee. In a few instances it also takes on the function of arranging for the postgraduate lectures. Many of the committees report very little activity, but in several of the larger societies this is the most active committee and accomplishes annually a vast amount of work in its community, either directly or indirectly through lay groups with which it affiliates. As an answer to the query as to whether the society takes a share in community group activities, forty-four reported that they do. Fifteen reported that they take no special interest in community affairs, since there are sufficient lay groups for the work. Two did not answer. The cooperation is generally conducted through the president and secretary of the society and appropriate committee chairmen. Eleven societies give the responsibility to the committee chairmen alone, while six make their contacts through the secretary of the society. In some societies this committee is combined with the committee on public relations. Thirty-five county societies, however, report having a separate committee on public relations. In eleven societies public relations and medical economics are combined, and in thirty-three societies medical economics is a separate committee. Forty-one societies have committees on workmen's compensation, and only ten have a public welfare committee.

The most important problem of both economics and compensation which presents itself to all societies throughout the state is that of proper and adequate medical care for the indigent. The state and federal governments are morally and financially interested in developing satisfactory working programs for the care of the aged, the indigent, and the fatherless child, and our county societies should all have committees actively working with the local authorities who are responsible for the administration of the laws regulating the work. The public authorities confess that they cannot satisfactorily administer the laws without advice and assistance from physicians.

Twenty-three societies have committees on maternity, infancy, and child hygiene, and twenty have cancer committees. Fifteen have program committees and thirteen have committees on membership. Eight have publicity committees, while five have committees on entertainment and arrangements.

part in county society programs, but they are no longer so liberal. Frequently a man who has mutually pleasant relations with the members of a county society will accept an invitation and expect no remuneration. Members of medical school faculties are still willing to assist societies in the vicinity of the schools. State employees can accept invitations and classify them among their duties, in which case the state will meet their expenses.

Other Expenditures

At least one-fourth of the societies provide a dinner at the time of the annual meeting with no extra charge to the members. All purchase floral pieces for their dead. Some honor their members with some significant gift on the completion of fifty years of practice.

A number of societies hold membership in one or more of the following organizations: Chamber of Commerce, Better Business Bureau, Tuberculosis Association, Council of Social Agencies, and Cancer Committee. Some make contributions to the Boy Scouts, Red Cross, Salvation Army, and Community Chest. Other items of expense mentioned by at least one society are auditing, interest, rent, insurance, library, social security, telephone and telegraph, bulletins, essay contest, broadcasts, projection lantern, travel, and collations. Six societies contribute from \$10 to \$25 to the Physicians' Home.

Committees

The most important committee of the societies is the *comitia minora*. All but a few of the smaller societies have a *comitia minora*. It is generally composed of the officers and censors and sometimes the chairmen of the standing committees, but occasionally some of its members are elected by the society to that one office only. Its functions are usually those of an executive committee and a board of trustees. It devises or passes upon all plans or programs of activity of the society. It usually supervises the expenditure of money and makes recommendations of administration to the society. Its time of meeting is generally within the week prior to the regular meeting of the society.

Every society has a legislative committee. In one of the large societies the committee has fifty members, while in some of the smaller societies the committee is but one person. From many aspects this is the most important committee of a society's organization. Annually, scores of bills are brought before the

legislature which, if enacted into law, would endanger the public health, interfere with the scientific practice of medicine, or compel our educational authorities to lower the enviable high standards of which New York State is so proud. It is well known that vicious proposals are often promoted by large, powerful groups and interests and not infrequently championed by intellectual and influential citizens. It, therefore, behooves every society (regardless of its size, rural or urban) to be responsible for bringing promptly to the attention of its legislators and other political leaders correct information on each such measure. The legislative committee is given this responsibility, and its personnel should be selected in a manner to make it most efficient. The chairman should be able and willing to give the time necessary to read and study the bills as they come before the legislature. He should be familiar with the political organizations of the county, and his efficiency will be greatly increased and his task lightened if he is personally acquainted with the legislators and political leaders. In the larger societies he cannot expect to know all of the leaders, and so he must delegate some of this responsibility to other members of his committee. Some societies compose their committees by selecting a physician from each legislative district of the county and giving him the personal responsibility of keeping in touch with that legislator. He is expected to enlist the aid of other physicians and influential public personages of the district when he feels their need.

It is now generally recognized by all societies that the most effective method of informing the legislators is not by the physicians sending mass telegrams or letters to everybody in the legislature or by appearing at the Capitol seeking to be heard on the relative merits and demerits of proposed legislation. Representatives of each society should discuss the important matters with their legislators when they are home over week-ends.

In order that the county society representatives may be familiar with pending legislation, the Legislative Committee of the State Society sends bulletins to each member of every county society legislative committee (weekly or more frequently if thought necessary) describing all bills relating to public health or the practice of medicine as they are introduced. These bulletins continue to report what action is taken upon the bills. The Executive Officer of the State Society calls upon the legislators in the Capitol and

were held Last year (1940) the conference was postponed because the secretaries had been called to Albany in July by the State Committee on Medical Preparedness Five county societies were represented by their secretaries at each of the nine conferences and three others by either the secretary or a substitute Six others were not represented at any one of the nine conferences either by their secretaries or substitutes Six were represented by their secretaries or substitutes at only one of the nine conferences (see Appendix)

Likewise, the State Committee on Legislation annually calls a conference in Albany in early February of the chairmen of the county society committees The object of the meeting is to study the bills that have been introduced in the legislature up to that time and decide whether to support or oppose them. At this time plans for continuance of the work through the session are formulated In the last ten years eight such conferences were held, one year there was no conference, and regional conferences were substituted as an experiment in one year Six societies have been represented at each of the eight conferences by their chairmen or appointed substitutes, and five were not represented at any Among the five are two societies whose secretaries were absent from all the secretaries' conferences as well Eight were represented at just one conference, six by the chairmen and two by substitutes (see Appendix)

The county society presidents have no opportunity to attend a statewide conference, but they meet in groups when they are invited to the conferences of the executive committees of the district branches Since the presidents serve but one term they cannot profit by acquaintance to the same degree as the secretaries or legislative chairmen who usually serve a number of years

Considering the observations in this study, it would seem that the medical profession is not so thoroughly organized in this state as it should be Spiritually and scientifically we are of one mind No society, regardless of its size or geographic location, will tolerate any violation or disregardance of the Code of Ethics, nor will it willingly or knowingly permit or contribute to any form of practice of medicine that does not promote and protect the public health The efficiency of these autonomous units can be increased by the State Society taking a more lively interest in the activities of the county societies The county society should retain its autonomy

and continue to be responsible for the medical activities within its boundaries, but many problems and situations arise in the administration of the Education, Health, and Welfare Laws that extend beyond the county and may be state-wide With such problems the best results are obtained by cooperation with the State Society Our respective standing committees do confer with representatives of the State Departments for the purpose of developing programs, but the methods of bringing a knowledge of the results of their deliberations to the county societies are faulty and ineffective Close cooperation between all of the county societies and Council committees so engaged is highly imperative, for the defection of a single society may be fatal to a desirable program As an example, the press announces that a member of the board of supervisors in a nearby county moved to reconsider its previous action in authorizing the appointment of a medical consultant to the welfare officer because members of the county medical society resented the appointment He said "They claim that nothing can be gained through the appointment of a medical consultant" The appointment of a medical consultant to assist the welfare officer is a recommendation of the Council Committee on Public Relations after two years' study of the Welfare Law and frequent consultations with representatives of the State Department of Social Welfare

Only by close cooperation among the county societies themselves and with the State Society can the physician members exert their greatest influence in public service The rapidly changing social relations and the threat of war demand that the medical profession join with other public agencies in defending our scientific achievements We have an unequalled opportunity to manifest our leadership by uniting to achieve the eight-point program of the American Medical Association, which is also our program, and to provide adequate medical care while many of our profession are in training camps If we neglect this opportunity for leadership, it will be assumed by lay and governmental agencies Since our leadership must depend upon the solidity of our organization, the following suggestions are offered (1) closer contact between state and all county societies, (2) full realization that problems of medical care and medical legislation are *fundamentally* the same in all counties, whether large or small, (3) free interchange of experiences among county societies and

The following are other committees mentioned, with the number of times they occur: advisory, 7, advisory to woman's auxiliary, 6, hearing, 2, hospital, 5, hospital insurance, 2, library, 4, medical indemnity, 3, milk, 3, nursing, 2, obituary, 4, physical therapy, 3, and speakers, 2. The following were mentioned once: auditing, grievance, illegal practice, journal management, laboratory, liaison, loan, nurse registry, ophthalmia, personal property, publications, public safety, radiology, relief fund, research, resolutions, scientific, T.E.R.A., visiting, and ways and means.

At the request of the State Committee on Medical Preparedness each county society has designated a special committee for that work.

Other Society Activities

Twenty-eight societies reported they have had one or more of the postgraduate courses of lectures and twenty-two have not had any. Eleven did not answer the question. The State Committee on Public Health and Education has reported elsewhere very fully on this activity.

A few years ago the Committee on Legislation recommended to the county societies that they invite the members of the local bar association to a joint meeting where matters of mutual interest might be discussed. Nineteen report that they have had such a joint meeting. Where there was no bar association they invited the district attorney, county judge, and other attorneys. Almost without exception the meeting was the occasion for a banquet. Now in some counties the physicians and attorneys take turns in acting as host annually. It has been observed that even one such affair has left a better feeling of mutual regard among those who were present. Nineteen societies have not had a joint meeting with the attorneys, and thirteen did not answer the question. Every society should make at least one effort to promote a spirit of good fellowship with associates in other professions in the community.

Eight societies employ executive secretaries and do not believe they could carry on their program without one. Forty-six have not considered having one because they think themselves too small to bear the expense and because they do not feel the need for one. Seven have considered the matter but fear the expense involved is too great. Twenty-nine would not consider employing one jointly with some other agency, while twenty-four are willing to consider such a proposition,

but sixteen of them doubt that there would be any advantage to the society.

These are not entirely unexpected reactions. Those larger societies that are meeting frequently and taking an interest in what their committees are doing are finding it increasingly difficult to secure a secretary who can contribute gratuitously the time required to attend meetings and conferences and send out notices to and for committees. It is very obvious that some societies are too small to bear alone the expense that would be involved in the employment of a full-time secretary, for not only would there be a salary to pay but it would be necessary to provide office space and equipment. However, if the small society finds it too difficult to employ an executive secretary, it should authorize its secretary and committee chairmen to employ stenographic services as required at the expense of the society. It should provide a means of interchanging ideas with public health and welfare agencies of the community. It should expect the chairmen of its committees to keep in touch with the corresponding committee chairmen of the State Society.

Can the State Society do more to help the county societies increase their usefulness? The outstanding assistance the State Society has been offering the county societies for the last fifteen or more years has been courses of lectures on all phases of medicine and surgery. The State Society Committee engages the lecturers, pays their transportation, and gives each a small honorarium. The county society need only provide the place of meeting and the audience, yet in these years only about two-thirds of the societies have availed themselves of the offer. The metropolitan counties prefer to provide their own courses.

Annually the State Society has conducted in Albany a conference with the secretaries of the county societies early in September before the fall meetings begin. The Society refunds to each secretary the entire expense incurred in making the trip. The average attendance is about one-half of the secretaries or delegated substitutes. Probably the programs have not been as valuable or attractive as they might have been, but one would expect the secretaries would welcome the opportunity to meet one another and interchange experiences, especially when the expenses are paid by the State Society. The secretaries from the larger counties are more likely to be present than those from the smaller societies.

In the last ten years nine such conferences

Maternal Welfare

From time to time under this heading articles will appear on obstetric subjects which are deemed of importance as aids to improvement of maternal welfare in New York State. The members of the committee are Charles A. Gordon, M.D., Chairman, James A. Quigley, M.D., and Ferdinand J. Schoeneck, M.D.

Prophylactic Forceps and Episiotomy

THE increasing use of prophylactic forceps and episiotomy would seem to call for a discussion of this subject. Some obstetric centers advocate this type of delivery as an almost routine procedure, whereas others condemn it quite wholeheartedly. All are in agreement, however, that if this type of delivery is used it must be a hospital procedure and should be performed by physicians who have had special training in operative obstetrics.

The late Pomeroy, of Brooklyn, introduced a method of delivery known as forceps control. This method consisted of applying forceps to the head after there was a considerable crown, the idea was to protect the perineum, and the procedure was employed when spontaneous delivery was anticipated within a comparatively short time. Pomeroy also advocated episiotomy as an adjunct for the same purpose. DeLee, of Chicago, popularized the term "prophylactic forceps." The indications for this operation, in addition to protecting the perineum, are generally considered to be of a prophylactic nature insofar as preventing cerebral damage to the baby. DeLee's contention is that a careful low forceps extraction with episiotomy puts less strain on the fetal cerebral structures than the pounding of the head against the perineum in the second stage. The fact that delivery may be performed sometime prior to that in which a spontaneous delivery would occur is also of analgesic value to the mother. It is conceded that there should be no pelvis-cephalic disproportion present. Both Pomeroy and DeLee received considerable opposition when they introduced their methods.

There seems to be little question that the use of episiotomies, especially when performed on primiparas, in the hands of trained obstetricians gives good anatomic results. A straight incision lends itself much more readily to anatomic approximation than does a ragged spontaneous laceration. The fact that the vast majority of primiparas will sustain perineal lacerations during delivery is conceded.

The application of forceps in the prophylactic forceps operation is comparatively simple, since the head is in an occipitoanterior position.

Is there any danger involved in the employment of prophylactic forceps? A careful consideration will show the answer to be yes. The primary danger would seem to center around infection. It must be remembered that where forceps are applied the tips of the blades pass

through the vagina and eventually come to rest within the lower portion of the uterine cavity. Hence, if the blades are contaminated or if there are pathogenic bacteria in the vagina, infection may be carried into the uterus. So, also, when the perineum is incised for an episiotomy, it is conceivable that infecting organisms may be transmitted into the wound. We must, therefore, be absolutely sure of our asepsis if we are to carry out this procedure safely. This would seem to limit the operation to the surgically clean, hospital delivery room. It has been shown time after time that any type of operative delivery is more prone to infection than normal spontaneous delivery.

Further danger may be said to center around the employment of forceps per se. Forceps, if improperly employed, may be brutal instruments, and it may truly be said that to use forceps properly is an art. In experienced hands they occasionally cause damage, in inexperienced hands they frequently are dangerous. The question involved is whether this type of low forceps extraction would cause more or less possibility of cerebral damage than spontaneous delivery. Parenthetically, it might be said in general that when we start improving on nature we are taking on a pretty large order.

As far as episiotomy is concerned, a practical anatomic understanding is essential. Median episiotomy or perineotomy is easy to perform and comparatively simple to repair. However, if employed in a short perineum, it may readily extend to involve the sphincter ani or even the rectum itself. On the other hand, the mediolateral or lateral episiotomy seldom extends to involve the rectum, although it may extend around it or may extend to involve the sulcus of the vagina. The proper repair of this lateral type of incision necessitates an intimate knowledge of the anatomy involved. There can be no question that a good repair of an episiotomy gives a nice anatomic result, on the other hand, a careful approximation of a spontaneous laceration is highly satisfactory from a practical point of view.

Common sense dictates that the results obtained from the employment of prophylactic forceps depends on the training and adeptness of the individual physician. There certainly can be no excuse for the employment of nominal prophylactic forceps, which is simply a low forceps extraction, to speed up delivery. This type of attitude can only lead to trouble.

SURGICAL INSTRUMENTS NEEDED

A letter from the Duchess of Leinster to the J A M A declares that "The situation in England is one of intense suffering. Surgical instruments and equipment are urgently needed NOW. Will you please help me to help the doctors and surgeons at home to relieve this suffering by publishing this letter together with the enclosed list of instruments? This list has just been flown across to me by clipper, from a source of highest authority in London."

"The instruments urgently needed in British first aid stations are

Airways, endotracheal	Pharyngoscope with
Apparatus, anesthetic (portable)	battery in handle
Apparatus, intravenous	Plates, bone
Aspirators	Pliers, side cutting, 6 inch
Autoclave	Probes, all types
Basins	Retractors, all types
Cabinets, instrument	Rings, laparotomy
Cannula, brain exploring	Saws, all types
Catheters	Scissors, all types
Chisels, bone	Screws, bone plating
Clamps, bone plating	Shears
Clamps, intestinal	Snare
Clips, towel	Sounds, metal
Curets, mastoid	Spatula
Diagnostic sets	Speculums, ear, eye, nasal, rectal
Depressors, tongue	Sphygmomanometer, aneroid
	Stands for irrigators
	Sterilizers, all

Directors, grooved with myrtle leaf	Stethoscopes
Drill, bone	Stools, anesthetists' with revolving top
Drills, cranial	Stools, foot
Elevators	Syringes, all sizes, with needles
Forceps, artery, all types	Tables, instrument
Forceps, bone, rongeurs	Tables, operating
Gags, mouth, Denhart	Trocars
Gorget, lithotomy	Tubes, tracheotomy
Gouges, bone	Wax, bone, sterile
Headbands, metal, with mirrors	Buckets
Hemostats, all types	Clippers, hair
Holders, needle	Cups, medicine
Inhalers, chloroform	Jugs, graduated
Knives, all types	Measures, glass, graduated
Lamps, operating, emergency, complete	Pans, bed, enamel
Mallets, metal, lead filled	Pitchers, 3 quart
Mirrors, laryngeal	Stoves, petrol or paraffin, table model
	Tables, bedside
	Urinals, E I

"I feel this is the quickest way to appeal to all doctors in the hope that they will read this and send their surplus instruments to me at the address below. All contributions will be sent to England at once, where they will help to save many lives that may otherwise be lost—
RAFAELLE LEINSTER, The Duchess of Leinster, Surgical Supplies, 745 Fifth Avenue, New York."

SOCIAL HYGIENE WEEK IN NEW YORK CITY

An expanded program of activities for New York City Social Hygiene Week—January 29 through February 6—is announced by the Bureau of Social Hygiene, New York City Department of Health. Meetings, film showings, demonstrations, lectures will be held, all of interest to physicians-in-practice, medical students, nurses, laboratory and public health workers, and the general public.

The activities are as follows:

January 29, 10 00 A M.—Laboratory Aspects of Syphilis Control, 1 00 P M.—The Role of the Family Physician in Venereal Disease Control, 2 30 P M.—Treatment of Infectious Syphilis as a Public Health Measure

January 30, 10 00 A M.—Nonsyphilitic Venereal Granulomas (chancroid, lymphogranuloma venereum, and granuloma inguinale), 1 00 P M.—Education of the Nonmedical Public Health Worker, 2 30 P M.—Nonvenereal Genital Lesions

January 31, 10 00 A M.—Laboratory Aspects of Gonorrhea Control, 1 00 P M.—Education of the Public on Venereal Disease Problems, 2 30 P M.—Treatment of the Patient with Gonorrhea

February 4, 8 30 P M.—*Clinical Syphilis* (This meeting will be held at The Academy of Medicine, 2 E 103rd St., New York City)

February 5, All-Day—*Social Hygiene Conference at Hotel Astor, New York City, 8 30 P M.*—Medical Advances in Venereal Diseases

February 6, 10 00 A M. to 4 00 P M.—Continuous program: lectures, motion pictures, playlets, and special events for the public

All sessions (except where otherwise noted) will be held in the auditorium on the second floor of the Health Department building, 125 Worth St., New York City. No registration is required.

The program is under the general supervision of Dr. C. C. Pierce, Regional Director for the U S Public Health Service. Cooperating agencies include the Section of Dermatology and Syphilology, Academy of Medicine, New York, New Jersey, and Connecticut state venereal disease control divisions, U S Public Health Service, Metropolitan Health Officers Association, and the five medical colleges in the city.

For detailed program write to Bureau of Social Hygiene, 125 Worth St., New York City

Medical Preparedness

Report of the Analysis of Physical Examination Form No 200 Representing
Partial Returns from 120 Local Boards, New York City Selective Service

Medical Bulletin No 1

THE first analysis of the physical examinations of men rejected by the examining physicians attached to New York City's local selective service boards and induction boards constitutes this report.

The report represents partial returns from 120 local boards. The total registrants examined number 1,643 of which 1,213 were accepted for general military service, leaving 430 rejected, some of whom were fit for limited duty only.

This report, which is a fair sampling of the rejects, does not show any specific deterioration in the population but rather enhances the fact that the general health of the community is good.

The report divides the analysis into primary and secondary causes for rejection. In addition to the primary cause for which a man was rejected, there were frequently other defects present, sometimes resulting from the main cause for rejection and sometimes merely being in addition to it.

The causes for rejections, listed in the report, follow:

Under the heading of developmental defects, which are 2.7 per cent of the total men examined, 26 were rejected for being underweight, a condition that was present in 17 in addition to the primary causes for rejection, 11 were rejected for overweight, and in 12 instances it was of secondary importance. Two were turned down for deficient height, and 1 was under the accepted height standard besides having a more important cause for rejection. None were rejected because of poor chest expansion, but 5 who were rejected for other reasons failed to meet the chest expansion requirements. One man was rejected for deformity of the head and 4 for deformity of the spine, while for 12 deformity of the spine was a secondary defect. None were rejected because of deformity of the chest alone, but in 3 it was a secondary condition.

Defective vision was the primary cause of 74 rejections (5 per cent of the total examined) and a secondary condition in 32.

One and four-tenths per cent of the total had ear troubles. Nineteen were rejected for chronic otitis media (chronic ear infection), and 4 had it in addition to other causes for rejection. Impaired hearing returned 4 to civilian life, and in the case of 9 it was a secondary condition.

Nose and throat troubles caused only 3 rejections (0.9 per cent of the total), and those for nasal defects. But 5 others had secondary nasal conditions, 3, infected tonsils, and 5, speech defects.

Teeth and mouth conditions caused more rejections than any other single cause (5.7 per cent of the total). Eighty-eight were rejected for insufficient teeth, and for 20 it was a secondary condition. Four men were rejected for disease of the gums, 1 had it in addition to another cause for rejection, and 1 man was rejected for deformity of the jaw.

Diseases of the heart were represented by 66 rejections. Acquired heart diseases were found

in 4.9 per cent of the total men examined. Fifteen were rejected for rheumatic heart disease, in 2 cases it was a secondary condition. Thirty were rejected for valvular heart disease, and 7 had it in addition to other causes for rejection. One was rejected for myocarditis, 8 for hypertension, and 3 for tachycardia, while 2, 21, and 12, respectively, had these cardiac defects while being rejected for other causes. Secondary to the cause for the man's rejection was 1 case of hypotension. Enlarged heart disqualified 3 for army life, and 9 suffered from it in addition to other causes for rejection. Three were rejected for an organic systolic heart murmur, and 6 had it as a secondary cause for rejection. One was rejected for angina pectoris.

Two were rejected for congenital heart disease (0.1 per cent of the total), while 1 suffered from it as a secondary condition to rejection.

Sixteen (1 per cent of the total), were rejected for hernia, and 9 had hernia in addition to other causes for rejection.

Few were rejected for stomach and intestinal troubles. Three were out because of peptic ulcers (0.2 per cent of the total), with 1 suffering from them as a secondary condition to rejection. Ten had hemorrhoids in addition to more serious conditions which caused their rejection, while 1 (0.06 per cent of the total) was rejected for an infected pilonidal sinus. One suffered from this but only as a secondary cause for rejection.

Genitourinary troubles accounted for very few rejections (0.4 per cent of the total). Four were rejected for large varicocele, and in 6 it was a secondary condition. Hydrocele was the secondary condition in 3 cases, and undescended testicle in 1 case, while it caused the actual rejection in 2.

Disease of the skin (0.06 per cent of the total) accounted for 1 rejection and was a secondary condition in 1 case.

Disabilities resulting from accidents accounted for 5 rejections (0.3 per cent of the total), 4, loss of limb, and 1, loss of toe or finger. The latter was a secondary condition for rejection in 1 case.

As the probable result of infantile paralysis, 28 were rejected (1.7 per cent of the total), 18 for paralysis of limb and 10 for deformity of limb. Three and 5, respectively, suffered these two conditions as a secondary cause for rejection.

Five men (0.3 per cent of the total) were rejected for defective joints, and in 1 case it was a secondary condition.

Foot and leg conditions caused relatively few rejections (0.3 per cent of the total). Two were rejected for varicose veins, and in 7 it was a secondary condition. Only 1 man was rejected because of flat feet, although 16 who were rejected for other causes also had them. Osteomyelitis deferred 2, and hammer toe was a secondary cause for deferment in 1 case.

Fifteen were rejected for chronic pulmonary tuberculosis and 1 for spontaneous pneumothorax (together 1 per cent of the total examined), while hemoptysis was found to be a secondary condition in 1 man.

Furthermore, not infrequently a delivery that promises to be simple becomes a very difficult extraction if the outlet has been misjudged. This may be true in spite of the fact that there is a considerable crown present.

Of course, each physician must be his own judge as to whether he will employ prophylactic forceps and episiotomy. In coming to a conclusion several factors must be considered. This procedure is an operative one and carries with it the dangers of any operative delivery. Adeptness with forceps depends on training and experience. Unquestionably, the improper application and faulty technique of extraction will give poor results.

Asepsis and anesthesia must be given due consideration. Certainly the physician assumes an added responsibility when he undertakes this type of artificial delivery.

In general it would appear that delivery by means of prophylactic forceps should be restricted to hospital deliveries by experienced obstetricians. One point is certain: any artificial method of delivery carries a higher morbidity risk as well as a higher fetal mortality rate than spontaneous delivery. Probably these factors, more than any others, should guide the physician in his decision as to whether or not he should employ prophylactic forceps.

DANGER OF "PICK-ME-UP" DRUGS

Because they merely mask fatigue rather than overcome it, the popular "pick-me-up" drugs lead the victim to draw unsuspectingly on energy reserves—a process that must sooner or later end in physical and nervous bankruptcy, Dr Iago Galdston, New York City, declares in *Hygeia*, *The Health Magazine* for October.

The "pick-me-up" addict is more likely to suffer from nervous fatigue than from exhaustion due to hard muscular labor, he points out. Two types of drugs are advertised to make an appeal to such sufferers: first, drugs such as caffeine, benzedrine sulfate, and alcohol that deaden the sense of fatigue and surround the victim with a false feeling of well-being, and second, more readily available fuel, such as dextrose, glucose, or their elements.

"The first type," the author says, "strikes dangerously at the central nervous system, the second, more pretentious in its claims, would make it appear that food, rather than rest, is the cure for fatigue. Both types are either superfluous and useless, or they do pick you up only to let you down with a terrible crash, perhaps at the risk of health."

Describing how the first type of "pick-me-up" works, Dr Galdston cites amphetamine sulfate, popularly known as benzedrine sulfate, a pep-producer widely used by students to keep them alert for "cramming sessions" before examinations. "In most persons," he says, "this drug raises blood pressure and increases heart action if

taken in sufficient dosage. The whole system may be thrown into a state of alarm, sensitivities are heightened, talkativeness increases markedly, a pronounced feeling of elation overtakes the person who, half an hour before, may have been jaded to exhaustion. Repose is impossible while the benzedrine sulfate brass band is playing. Then suddenly the music stops, and the deluded pep-chaser finds himself 'dropped out of the window.' More and more pills are taken as the addict tries to stave off the inevitable energy collapse. Jaded nerves are flogged into further efforts, heart and brain are teased beyond normal capacity.

"The company that manufactures benzedrine is a reputable pharmaceutical house, it is emphatically not to blame for the indiscriminate and unsupervised use of this drug.

"We should regard normal fatigue not as an enemy but as a warning cry. Because it has such a vital bearing on industrial efficiency, accident and sickness rates, it has been intensively studied in many places throughout the world. It is significant that none of the fatigue laboratories of the world has ever recommended or manufactured a patented pick-me-up."

"The ideal method of avoiding undue fatigue is a regulated program of rest, work, and recreation. If you are doing too much, cut down on your activities. On the other hand, if you are already husbanding your energy and yet find yourself unduly fatigued, what you need is a good doctor."

MEDICOMILITARY CONFERENCE

A symposium under the auspices of the 205th General Hospital (RAI) and the 4th Hospital Center (RAI) on the Psychiatric Aspects of Military Medicine will be given at the Psychiatric Division of Bellevue Hospital (Foot of East 30th Street, New York City) on Tuesday, February 4, 1941, at 8:30 P.M.

The program will be as follows: (1) Introductory Remarks by Dr Leo L. Orenstein, 1st Lt. Med.-Res., U.S. Army, (2) "The Army Medical Officer Looks at Psychiatry," Dr Samuel Adams Cohen, Col. Med.-Res., U.S. Army, Commanding 205th General Hospital, presiding, (3) "Psychiatric Examinations in the Armed Forces," by Dr Karl M. Bowman, Lt. Comdr. M.C., U.S.N.R., (4) "Neuroses of War," by Dr Abram Kardiner, (5) "The War of

Nerves," by Dr Sandor Rado, (6) "A Brief Consideration of the Psychoneuroses of the Last War and What We Might Expect in the New Order of Things in This Country," by Dr Edwin G. Zabriskie, Lt. Col. Med. Corps, formerly Consultant in Neuropsychiatry, First Army A.E.F.

(7) The discussion will be opened by Dr Francis M. Shockley, Lt. Col. Med.-Res., U.S. Army, Dr Clarence P. Oberndorf, and Dr George E. Daniels. (8) The concluding remarks will be made by Dr Joseph Haas, Lt. Col. Med.-Res., U.S. Army, Commanding 4th Hospital Center.

Officers and prospective officers of medical departments of the armed forces are cordially invited to be present.

Medical Preparedness

Report of the Analysis of Physical Examination Form No 200 Representing Partial Returns from 120 Local Boards, New York City Selective Service

Medical Bulletin No 1

THE first analysis of the physical examinations of men rejected by the examining physicians attached to New York City's local selective service boards and induction boards constitutes this report.

The report represents partial returns from 120 local boards. The total registrants examined number 1,643 of which 1,213 were accepted for general military service, leaving 430 rejected, some of whom were fit for limited duty only.

This report, which is a fair sampling of the rejects, does not show any specific deterioration in the population but rather enhances the fact that the general health of the community is good.

The report divides the analysis into primary and secondary causes for rejection. In addition to the primary cause for which a man was rejected, there were frequently other defects present, sometimes resulting from the main cause for rejection and sometimes merely being in addition to it.

The causes for rejections, listed in the report, follow.

Under the heading of developmental defects, which are 2.7 per cent of the total men examined, 26 were rejected for being underweight, a condition that was present in 17 in addition to the primary causes for rejection, 11 were rejected for overweight, and in 12 instances it was of secondary importance. Two were turned down for deficient height, and 1 was under the accepted height standard besides having a more important cause for rejection. None were rejected because of poor chest expansion, but 5 who were rejected for other reasons failed to meet the chest expansion requirements. One man was rejected for deformity of the head and 4 for deformity of the spine, while for 12 deformity of the spine was a secondary defect. None were rejected because of deformity of the chest alone, but in 3 it was a secondary condition.

Defective vision was the primary cause of 74 rejections (5 per cent of the total examined) and a secondary condition in 32.

One and four-tenths per cent of the total had ear troubles. Nineteen were rejected for chronic otitis media (chronic ear infection), and 4 had it in addition to other causes for rejection. Impaired hearing returned 4 to civilian life, and in the case of 9 it was a secondary condition.

Nose and throat troubles caused only 3 rejections (0.9 per cent of the total), and those for nasal defects. But 5 others had secondary nasal conditions, 3, infected tonsils, and 5, speech defects.

Teeth and mouth conditions caused more rejections than any other single cause (5.7 per cent of the total). Eighty-eight were rejected for insufficient teeth, and for 20 it was a secondary condition. Four men were rejected for disease of the gums, 1 had it in addition to another cause for rejection, and 1 man was rejected for deformity of the jaw.

Diseases of the heart were represented by 66 rejections. Acquired heart diseases were found

in 4.9 per cent of the total men examined. Fifteen were rejected for rheumatic heart disease, in 2 cases it was a secondary condition. Thirty were rejected for valvular heart disease, and 7 had it in addition to other causes for rejection. One was rejected for myocarditis, 8 for hypertension, and 3 for tachycardia, while 2, 21, and 12, respectively, had these cardiac defects while being rejected for other causes. Secondary to the cause for the man's rejection was 1 case of hypotension. Enlarged heart disqualified 3 for army life, and 9 suffered from it in addition to other causes for rejection. Three were rejected for an organic systolic heart murmur, and 6 had it as a secondary cause for rejection. One was rejected for angina pectoris.

Two were rejected for congenital heart disease (0.1 per cent of the total), while 1 suffered from it as a secondary condition to rejection.

Sixteen (1 per cent of the total), were rejected for hernia, and 9 had hernia in addition to other causes for rejection.

Few were rejected for stomach and intestinal troubles. Three were out because of peptic ulcers (0.2 per cent of the total), with 1 suffering from them as a secondary condition to rejection. Ten had hemorrhoids in addition to more serious conditions which caused their rejection, while 1 (0.06 per cent of the total) was rejected for an infected pilonidal sinus. One suffered from this but only as a secondary cause for rejection.

Genitourinary troubles accounted for very few rejections (0.4 per cent of the total). Four were rejected for large varicocele, and in 6 it was a secondary condition. Hydrocele was the secondary condition in 3 cases, and undescended testicle in 1 case, while it caused the actual rejection in 2.

Disease of the skin (0.06 per cent of the total) accounted for 1 rejection and was a secondary condition in 1 case.

Disabilities resulting from accidents accounted for 5 rejections (0.3 per cent of the total), 4, loss of limb, and 1, loss of toe or finger. The latter was a secondary condition for rejection in 1 case.

As the probable result of infantile paralysis, 28 were rejected (1.7 per cent of the total), 18 for paralysis of limb and 10 for deformity of limb. Three and 5, respectively, suffered these two conditions as a secondary cause for rejection.

Five men (0.3 per cent of the total) were rejected for defective joints, and in 1 case it was a secondary condition.

Foot and leg conditions caused relatively few rejections (0.3 per cent of the total). Two were rejected for varicose veins, and in 7 it was a secondary condition. Only 1 man was rejected because of flat feet, although 16 who were rejected for other causes also had them. Osteomyelitis deferred 2, and hammer toe was a secondary cause for deferment in 1 case.

Fifteen were rejected for chronic pulmonary tuberculosis and 1 for spontaneous pneumothorax (together 1 per cent of the total examined), while hemoptysis was found to be a secondary condition in 1 man.

Under the heading of chronic lung conditions not due to tuberculosis (0.2 per cent of the total), the report to Colonel McDermott showed that there were 2 rejections for chronic bronchitis, while 1 man suffered from it in addition to the primary cause for rejection. There was 1 rejection for bronchial asthma and 1 for pleurisy.

Only 6 men (0.4 per cent of the total) were rejected because of syphilis, but there were 90 cases of a positive Wassermann which deferred the men in question until they could be re-examined. There were 26 causes of doubtful Wassermanns on the basis of which the men were deferred until further examinations could be made. Gonorrhea was present in only 1 case, and then it was a secondary cause for rejection.

Two men had albumin in the urine, but this was not the primary cause for rejection.

Two men (0.1 per cent of the total) were rejected for chronic nephritis.

The report shows 8 cases of rejection for diabetes mellitus and 1 for persistent glycosuria (together 0.5 per cent of the total), although in 6 this latter condition was present in addition to a primary cause for rejection.

Endocrine gland disturbances accounted for 2 rejections (0.1 per cent of the total), 2 men with cases of toxic thyroid. This condition was present in 2 other cases in addition to the primary causes for deferment, as was Froehlich's syndrome in 1 case.

Diseases of the blood, chronic myelogenous leukemia, and secondary anemia accounted for 1 rejection because of the first condition (0.06 per cent of the total), while secondary anemia was found to be present in 7 cases deferred for other reasons.

Psychiatric problems presented 0.8 per cent of the total and led to the deferment of 12 mental defectives and 1 man for nervous instability. Four men were mentally defective, although they were deferred for other reasons.

Nerve diseases (0.2 per cent of the men examined) were the cause of 4 deferments—1 for facial paralysis, 1 for ataxia, and 2 for epilepsy. One cause of trigeminal neuralgia was found, but it was a secondary cause for deferment.

Comment

The major causes for rejection can be divided into the following groups:

1. Developmental defects, such as defective vision, congenital deformities, and mental deficiencies.
2. Neglect which results in chronic otitis media, underweight and overweight, and insufficient teeth.
3. Traumatic causes, the result either of athletic or other exercise or type of employment and producing hernias, flat feet, etc.
4. Diseases as yet not conquered by medicine, such as rheumatic and valvular heart disease, hypertension, and the results of infantile paralysis and pulmonary tuberculosis.

It is surprising to note the small number of glandular disturbances, blood dyscrasias, pulmonary lesions, and cardiac disturbances. On the basis of these figures it is possible to draw the following conclusions:

1. In the age period between 21 and 35,

the general health of the population seems to be good.

2. This good medical health is apparent from the fact that most of the faults (except those due to neglect) are irremediable under the best conditions in medical practice, and it is all the more striking that the figures show up as they do because these people have lived through a period of almost ten years of economic and mental stress which at times necessitates the curtailment of adequate diet, proper housing, and other facilities. There is very little evidence to show that acute illnesses have left permanent bad aftereffects due to the absence of adequate medical care.
3. One can conclude from these figures that a general health program should be so directed as to stress prevention and bring to the younger people of the nation supervision and instruction on how to preserve their teeth, how to stop incipient cases, and how to handle the beginnings of lesions in the gums which eventually will cause the loss of masticating teeth. Likewise, the misuse of their eyes, resulting in the number of visual defects, would make it seem that an educational program on the preservation of eyesight might be included in such a program directed toward the high-school age boys, all with the idea of stressing prevention, as the foregoing has been a large factor in causing rejections.

Finally, more attention should be paid to correcting the industrial hazards of health, and an intense antivenerical campaign with special stress on prevention seems to be indicated.

In conclusion, it must be reiterated that this report is but "a sampling" of the returns available to date. It is proposed to issue continuing reports as more material for statistical study becomes available. The conclusions drawn must, at this time, be considered as tentative. If substantiated by subsequent surveys and paralleled from selective service headquarters throughout the country, a better estimation of the health of this age group in the population will be available than from any heretofore at our disposition. This survey has the added value in that two sets of medical examiners have collaborated to produce the record—the first, the local board examining physician and his medical advisory board of specialists, and the second, physical check-up by the board of specialists at the army induction centers.

Respectfully submitted,
SAMUEL J. KOPETZKY
Colonel—MCR—USA
Medical Division

THE DETAILED CAUSES OF REJECTIONS			
Total Registrants Examined			1,643
Accepted for General Military Service			1,313
Rejected for General Military Service (Fit for limited duty only or rejected)			430

American Alumni of British Medical Schools

30 Rockefeller Plaza, New York, N. Y.

December 18th, 1940

Dr Samuel J. Kopetzky
Council Committee on Medical Preparedness
71 East 80th Street
New York, N. Y.

Dear Doctor Kopetzky:

In the December 15th issue of the *NEW YORK STATE MEDICAL JOURNAL*, the Council Committee on Medical Preparedness states on page 1805 the following:

"It should be understood by all that an Army Regulation such as this can be changed only by the President or the Secretary of War. What the possibility of such action there may be is entirely unknown to the Council."

The above refers in part to the physicians who have been graduated from the foreign medical schools.

The Council should be advised that a committee was sent to Washington by this Alumni. On November 18, 1940, this committee was informed, during the course of an interview by the Surgeon General's executive assistant, that the Army Regulation is not an Act of Congress but a ruling made by the Surgeon General of the Army. The ruling was made to prevent physicians who were graduated from medical schools abroad which do not compare favorably with those schools approved by the Council on Medical Education and Hospitals of the American Medical Association. The Surgeon General's executive assistant stated that no information has been made available to the Surgeon General, hence no opinion can be made on the many foreign medical schools. He further stated that in the past graduates from the foreign medical schools have been commissioned in the Reserve. If information is made available and

if the foreign medical schools compare favorably with the Grade A medical schools from the United States and Canada, then the Army Regulation *may be amended* so that those graduates from the foreign medical schools *may be commissioned in the medical corps* of the Reserve. Those physicians who are conscripted will be conscripted as privates. However, they may immediately apply for a commission to their local commander and each case will be judged on its merit.

In the course of an interview with the assistant to the Assistant Secretary of War, on November 18, 1940, the committee was informed that an Army Regulation concerning the medical corps is initiated by the Surgeon General of the Army. Any change in the Army Regulation must be initiated by the Surgeon General of the Army.

Hence the quotation appearing above is misinforming the readers of the *JOURNAL*.

This Alumni would like to point out that the medical societies from the counties of the Bronx, Kings, New York, Queens, and Nassau adopted resolutions during the month of October, 1940, indicating gross dissatisfaction with the Army Regulation and its effect on the graduates from the foreign medical schools. The county societies urged that the Regulation be rescinded.

This Alumni would be pleased to have the Council Committee on Medical Preparedness from the State of New York reveal what has been done to answer the 10,571 members of the above societies. This figure comprises 59.7 per cent of the membership of the Medical Society of the State of New York. These figures were taken from the Medical Directory of New York, New Jersey, and Connecticut, 1939-1940.

Yours very truly,
LEON L. RACKOW, M.D.
Vice-Chairman, Executive Committee

Medical News

Testimonial Dinner for Dr James M. Flynn

THE Monroe County Medical Society for its annual meeting on December 17, 1940, arranged a dinner in honor of the president of the Medical Society of the State of New York, Dr James M Flynn. The dinner took place in the Rochester Academy of Medicine.

Dr Albert D Kaiser, president of the Monroe County Medical Society, in his opening remarks called attention to the fact that this was the one hundred and twentieth annual meeting of the county society.

"It is rather interesting," Dr Kaiser said, "when one reviews the early motives that existed in the minds of the doctors who founded this county medical society and undoubtedly many others throughout the country. The doctors of a hundred or more years ago found that it was necessary to have some sort of an organization in which they could regulate their own practice and in which they could supervise the work of their practitioners.

"I am quite sure that their purpose has prompted the organized medical societies throughout these many decades. The idea of the county medical society spread to the state and finally to the nation.

"It is rather interesting to look back over the last twenty-five or thirty years to see the trend of medicine. The discoveries in medical science have made it necessary to break up the medical profession. We have teachers, investigators, clinicians, hospital directors, and public health officials, all of them doctors, but all of them engaged in a fairly highly specialized field, to say nothing of the many specialists in the field of clinical medicine.

"I think there has been a tendency in recent years on the part of some physicians to belittle the importance of organized medical societies. They see perhaps only their own interests and are perhaps a little intolerant of what the man does in another field. I am quite sure that when we see medicine in its broad aspect, no one department could exist without the others. And every physician should realize that the organized medical society tends to bring together all of the groups that are associated with the practice and development of medical science.

"I am very glad that I have had some experience in the last few years with what organized medical societies aim to do. I believe that it is only by uniting our efforts and pooling the things which we can contribute to a medical society that we can reach the utmost usefulness in the field of medicine.

"Every county medical society is proud of its members, because the first thing we try to do is to improve conditions for the average man. But we also like to see exceptional effort on the part

of some of the members. I for one feel very proud of our society here in Monroe County, that we have had outstanding men in this society who have contributed to various fields of medical endeavor.

"Tonight we are gathered here for a specific purpose, because one of our men has had a vision—he has looked ahead—he has given of his time and effort to build along the lines of organizations from which we can all benefit. As members of this society we are proud that one of our men has distinguished himself and has brought honor to this society.

"So tonight we are welcoming our guests who are celebrating with us the success of Dr Flynn in reaching the highest peak in the gift of the doctors of the State of New York. We are very happy that men have come from afar to talk briefly to us not only about Dr Flynn but about some of the problems of medicine."

Mr Roland B Woodward, executive vice-president of the Rochester Chamber of Commerce and a member of the Board of Regents of the State Department of Education, was then introduced.

"I am very happy to be here and add my word of felicitation to that of many others for Dr Flynn and the honor which you do him tonight. My own association with him has been very pleasant. He has helped me and advised me on some problems that have confronted the Board of Regents, and I have found his advice sound and honest and helpful.

"I remember speaking before a group of you when you were celebrating the opening of this building, and stressing the need for your taking some interest in public affairs, but I mean public affairs as they affect the things which you know best, as they affect your professional group, as they affect legislation that controls or directs or limits your usefulness. It will not do for our highly educated professional men to draw aside from our public life and allow all of it to be done by those who perhaps know little or nothing about the things with which they are vitally concerned.

"I have learned quite a bit about this in sixteen years of service on the Board of Regents. The state is deeply concerned with the education of the physician, with his licensure, with the rules and regulations that govern his practice. And they are especially concerned with his capacity for self-government professionally. And I am happy to say that having dealt with all the professions that are licensed by the State of New York, I think there is no professional group in the state that has approached so nearly to a good degree of self-government as the medical profession.

Left to right Albert D. Kaiser, M.D., president of the Monroe County Medical Society, Nathan B. Van Etten, M.D., president of the American Medical Association, James M. Flynn, M.D., president of the Medical Society of the State of New York, C. Stewart Nash, M.D., vice-president of the Monroe County Medical Society

"With the problems ahead, it is very important that you continue to do so and that you continue to do so with increasing effectiveness, unless you would have imposed upon you something that would not only handicap you in your work but which would restrict your value to the great public which you serve

"Dr. Flynn, you are a good example of what I am talking about, and I am happy to add a word of tribute to your public usefulness as well as your professional competence and professional usefulness. I congratulate you and wish you many more years of such useful service."

Dr. Leo F. Simpson of Rochester was then called on.

"I have been asked to say a few words about Jim, the Boy and the Man. That, I suppose, is based on the idea that the man is in the boy. What the man ultimately becomes is undoubtedly in the boy—in potentia—but so, in like manner, a thousand other men are in the same boy.

"Heredity may lay down the instrument, but environment more or less determines the kind of a tune that is to be played on it during the years.

"We, in medicine, are ever considering the possibility of modifying even the instrument itself, while educators, biochemists, students of social welfare, and the great religious movements are ever confident of their ability to change the

resulting tune for the better. A sort of conditioning the reflexes, as it were.

"One cannot, however, be dogmatic in these fields for they are filled with unpredictable surprises. At one end we see Benjamin Franklin, one of the greatest all-around intellects America has ever produced—the man who almost single-handed won our American Revolution—in the Masonic lodges of France. He was the last child of fourteen children, and his whole family, by comparison, was a total blank.

"At the other end, we see the rapid disintegration of fine, cultural stocks because biological honesty does not necessarily co-exist with cultural fineness. Too often, when certain cultural limitations have been reached, racial suicide follows almost automatically.

"But what has all this to do with Jim? I will, for a few moments, take a passing glance at his heredity, his boyhood education, and also trace some behavior patterns that foretold the man. Of the sources of the urges that moved him onward, make your own guess. Ambition may be nothing but unsatisfied chemistry, or it may be a holy fire.

"We were born within a stone's throw of each other, of mothers whom each always thought were saints on earth, and know today are the same in heaven. Our fathers were grand men, in fact, they were the best that we could find.

"We played together as children, went to the

same school, where in addition to the three R's, they tried to teach us that there was a Supreme Authority above all from which all authority should flow, that the Ten Commandments were real and not just a bit of literature, and that we were not created for this world alone.

"These teachings have played a very fundamental part in Jim's life.

"Incidentally, a total disregard of such beliefs by the leaders of men bids fair to transform this world into a slaughterhouse.

"We got plenty of old-fashioned discipline, and as there were six children in each family our opportunities for becoming self-centered were rather limited.

"My real association with Jim began over forty years ago when we were carrier boys for the *Democrat & Chronicle*. We had to be at the office at 4 00 A M. As we lived in the far north-western part of the city that meant a jaunt of at least six miles before we completed our deliveries and got home again.

"My mother would drag me out of bed at three o'clock and many times I was not fully awake until I got out into the air. Coming to Jim's house, just a whistle, a window went up, and he would call 'I'll be right down.' He apparently never slept then, nor has he been caught asleep very often since. We did this for four years, every day in the week, starting at about thirteen years of age. It never seemed a hardship. Didn't we get a dollar and a half a week? Such jobs were priceless. Night street cars were unknown, and if a snowstorm was on we just waded through.

"We were prepared for anything the weather man had in stock, but even he, at times, was kind. A few hundred beautiful sunrises were shown, and as there was no one else about, it was easy to imagine that they were put on for our special benefit. And, so to bed again at seven, up at eight, and we would make our way back to Fitzhugh Street to the Rochester Free Academy, this time carrying our lunch.

"In the winter, after school, we played handball at the old R.A.C., and in the summer and fall played baseball and football. We had fine teams. Did I say we played baseball and football? I played, and in the fall kept pretty well bruised most of the time. What was Jim doing? He was starting in life. He was always the manager, and looked after the receipts.

"After graduation from carrying papers and high schools, I studied medicine, and graduated at twenty-one. One day, a few years later, Jim came into my office, and announced that he was going to study medicine. Where had he been, and what had he done to develop the rugged individualism that was as obvious then as it is today?

"For a year or two he had worked at, and I believe became a first-class clothing cutter. But that did not satisfy him. His experience as a high school manager, and as manager of several amateur teams made the life of a clothing cutter monotonous, and abruptly he cut himself away from his

moorings, and became manager for three minor league baseball clubs in succession—always advancing. His last team, on their first road trip, won ten games straight. They were received, when they returned, by all the city fathers and a band. On the next road trip they lost nine games, all by one run. On the day after he returned from that trip, Jim was fired.

"It was midsummer and no time to go home. He went to a telegraph office and sent telegrams to the president of every baseball league in the United States, which read 'James Flynn, umpire, now available for contract.' He got three answers. He had solved his baseball problem. He would make a fine living, no matter which team won.

"Eventually he was transferred to the Pacific Coast League. The president was located in Chicago, and his parting words to Jim were 'No one out there can fire you. You'll have to quit yourself.'

"He found out later just what that message meant. He went to leagues where baseball was a war, and where the word 'fan' was evolved from the fanatics in the stands who wavered between cheers and homicide. Umpires withered, ran out, and even wore out, but Jim stayed three years.

"He never smoked, never drank, and never read the sporting pages, said his prayers at night, and with these prophylactic measures faced the next day. One umpire to a game, and the decisions were roared with a finality, the echoes of which still linger.

"In this tempestuous atmosphere he passed his days until the time came for another momentous decision. As usual, the decision stood. This time it was to study medicine. He had been taking courses at Leland Stanford University between seasons and without hesitation he again cut his moorings.

"After graduation and his internship, he became an x-ray specialist. Now I think I have brought him to man's estate.

"He translated to the higher field of medicine the same qualities that made him what he was before. He has continued to grow in stature. He holds fast to what he knows is good. He knows the rules and obeys them. He is courageous. He renders the type of service that a faithful man always renders so he may live in peace with himself. As a rugged individualist he did not separate himself from the herd, but became a most important part of it.

"I have never known him to be envious of any man, nor hesitate at any opportunity for charity. He loves his profession, and has fought for its ideals and for its honor and independence these many years.

"It has been a great pleasure, and great fun, too, for me to have been a shipmate with Jim as we sailed down the river of life. Were I again at the starting, and gifted with adequate foresight, I would, without hesitation, step again into the same boat."

Dr E T Wentworth of Rochester described Dr Flynn as a "Straight Shooter," saying

"Jim Flynn"—the very name strikes out, straight, sharp, straight to the point. He is a four-square, straight-shooting, fearless man of God. The truth burns from him in fiery words—words with poignancy and a sharp sting, words that cut down through the years from Chaucer and beyond—good old English words—words from the limbo of freudian familiarity with certain biological functions. Words which without benefit of printing press, script, or lexicon, have been passed on from father to son—not from mother to son—but the meaning of which is crystal clear.

"Jim's straight line is the shortest distance between two points. He is a man of action. He does things rather than talk about them.

"The most commented upon speech of the many given in the Waldorf-Astoria at the last meeting of the A.M.A. was Jim Flynn's. There, concentrated upon that stage, were the men of the hour—the Governor of the State, the Mayor of the City, the Bishop of the Diocese, the Presidents of the two largest medical organizations in the world, the Commander of the Brooklyn Jewish War Veterans. I, too, was in that audience. I heard that speech. I learned it verbatim. I remember it as an example of perfect platform oratory.

"You can't get the full effect of a speech like that, reading it in your study. You have to have heard it, you have to have seen it, you have to have felt it, you have to know it. A mystic, impending feeling—a dynamic force—permeated the atmosphere the moment he rose from his chair and it increased as he strode toward the lectern.

"In every stride, in every fluid wave of that paunch, in every flicker of those bushy gray eyebrows, you could tell he had a mission to fulfill, and so help him God, he would fulfill it.

"The speech. Ladies and gentlemen, on behalf of the Medical Society of the State of New York, greetings." End of quotation—end of speech.

"Yet, seriously, all that he does shines with the chaste honor that would be crushed by stain as lovely virtue by ugly rape. He hates sham, he hates academic affectation and pretense, he hates professional posing and racketeers—those who dispense half-truths for whole truths, for honor is in the blood of him."

Dr Samuel J Kopetzky, of New York, president-elect of the State Medical Society, discussed "Flynn as I know him." He said

"Membership in a county society and activity in organized medicine bring a reward far beyond the scope of the activities that the individual engages in. One of the finest things that one gets in working within the ranks of organized medicine is the privilege and honor of knowing the men who are active in the profession.

"One of the things that I am very thankful for

is this opportunity which expressed itself in my acquaintance with men like Jim Flynn. For some years the rough toss and tumble of the political field within our State Society brought me to the chair of the speakership of the House of Delegates, and I found always sitting at my right during my whole term a man who quietly, unobtrusively sat there but at the right moment and in the turmoil of the House said the right and potent word to me.

"Jim Flynn has the essential element of leadership, he has initiative, he has courage, he has personality, he has tolerance for the stupid and the fool, and he has a distinct goal toward which he drives. Yet his leadership is so consummate that the effort is not seen, and the organization that he serves moves toward its appointed goal.

"Underneath all that you see of Jim Flynn there is a sterling honesty that is as refreshing as an early morn in spring. He is a fine man. I have no desire to make this talk too saccharine, but I do want to say that were Rochester many more miles from New York and I could walk or ride to get there to pay tribute to this man, I would break my neck to get there. And I am proud of the fact that I am able to serve the Society and you with Jim Flynn."

Dr Nathan B Van Etten, president of the American Medical Association, after bringing his tribute of friendship and admiration to Dr Flynn, gave the following address

Medical Futures

The Society is growing stronger every day—all of its programs of education are better than before. Its JOURNAL is gaining the place that it deserves. Its preparedness program has no superior, and its public relations program is applauded all over the nation.

Dr Flynn is generous to all who play the game honestly but fiercely intolerant of any effort to gain objectives by crookedness or quackery. He always works for the best interests of American medicine and I am sure that he will carry on as an indomitable force for many years to come.

Ninety-four years of fighting for the honest application of scientific knowledge to the demands of health for all people has earned the American Medical Association to the strongest position among medical organizations. Although its membership represents every shade of political complexion, partisanship has never dominated its patriotism. Its horizons extend far beyond election days. It will not sell out to political expediency. It will not sell out the idealism that has carried it through many crises.

It is preparing for the defense of Americanism against the attacks of paganism. It is preparing for maintenance of an advanced democracy unhampered by the subversive influence of foreign autocracies. It fights for the supremacy of the American way of life.

Although every type of religionist is included in its roster, it looks to all of them for loyalty to

one ideal of protection and promotion of human health. Cherishing the highest ideals of the most learned profession, it will not sell out to paganistic nihilism. It respects all religionists who are loyal to their beliefs. It believes that devotion to religious precepts is valuable and necessary relief for the loneliness of individualism.

Serving every social level it sympathizes warmly with all who are physically or mentally unfortunate.

Although its membership represents the descendants of every race, its fundamental interests are American. Recognizing the cosmopolitan character of a nation built from its beginnings by refugees from persecutions and intolerances, its hospitality has been continuously generous toward the mental and religious attitudes of the more recent seekers for freedom in our country. Although it respects the natural affection of newcomers for the traditions under which their life patterns have been formed, it believes that all should adapt themselves as soon as possible to national programs which have evolved the American way of life and that all should cooperate in its growth and improvement.

Although the American Medical Association may be justified in pride of accomplishment, it is not prejudiced against any earnest approach to new solutions of administrative or scientific problems. It insists upon complete and honest analyses of all new proposals before accepting and endorsing them.

It welcomes the restless spirit of scientific adventure and encourages it. It has spent more than a million dollars in research in the last twenty-five years. At the same time, however, it has been inflexible in its disapproval of those who would profit from the credulity of ignorance. It has never sold out to commercialism. It believes that Americanism is worthwhile. It cherishes the ideals of orderly democracy. It despises the devious ways of disloyal propagandists not only in the field of medical service but in civic life. It is conscious of the campaign of German sabotage which has been carried on with diplomatic immunity since 1915. It remembers the efforts of the brilliant Count Von Bernsdorf to seduce the Wilson administration and the violent sabotage of Von Papen and Captain Boy-ed, the same Von Papen now operating in Turkey. It knows that the same things are going on here at this moment. It knows that Russian communism and German socialism have been active here for many years.

It knows that the infiltration of foreign thought has fermented discontent in this country, so that some Americans have been led into disloyalty and are now working for the destruction of our democracy. It knows that American generosity has been so grossly abused that world revolution is being promoted.

The health program of the American Medical Association is an evolutionary development which fortunately escaped in large measure the acquisitive eye of the log-rolling politician until

the last few years, when job seekers, awakening to the possibilities of expanding bureaucracies, began stimulating the superficial humanitarianisms of political leaders.

As a consequence, the problem of the future health of all our people is being attacked by amateur philosophers who know nothing about the personal practice of medicine and who know about mass medicine only from superficial observation of foreign systems, none of which have improved the quality of medical service or have produced anything superior to our present system in the United States in 1940.

No one claims perfection for our system of delivery of medical service, but all of you know that the American Medical Association has been working for ninety-four years to improve it, that its chief concern is better health for all our people, and that nowhere on earth have better results been attained.

We have good reason to be proud of the fact that the science of medicine has steadily advanced the health of the American people and that, so far, the legal establishment of any of the foreign systems has been successfully resisted.

In spite of the undisputed fact that American health statistics are unsurpassed, the position of the physician in American society has become increasingly difficult because political theorists in social science have formed pressure groups whose object is to force legislative action to promote governmental control of medical service. Government in medicine, like the government in business, is just another step from democracy toward totalitarianism.

The thought of dictatorship in America is revolting. And yet, appeals to popular emotion under the aegis of patriotism, of social security, of pensions, of welfare, of relief, of unemployment, or of the people's health have carried many people from confidence in their ability to take care of themselves to belief that they have no personal responsibility for providing the sources of paternalism they expect to enjoy. They believe that they will drink forever from the inexhaustible wellsprings of government.

Dictatorships have been built on such public sentiment. If such sentiments prevail, the medical profession may well expect a fate similar to that which developed in Germany and reduced German physicians, as well as the German people, to economic slavery.

The physicians of the United States have made history. Campaigns against tuberculosis and diphtheria and pneumonia and syphilis have changed the health statistics of the nation to figures that could not have been predicted twenty years ago.

We know that an intelligent medical profession can educate the people in personal and community health. We know that education has been largely responsible for lowering the statistics of tuberculosis. We know that diphtheria can be entirely eradicated if the people will have enough intelligence to listen to the advice of the

doctor and immunize every child. We know that smallpox can be entirely eliminated by universal vaccination. We know that great gains have been made during the campaign against syphilis started by General Parran. We are confident that studies of immunology will salvage more and more people from the ravages of communicable disease.

These have been great years in the warfare of science, and, because our frontiers have been so remarkably advanced, we might be justified in predicting greater triumphs if the future of our civilization were not threatened by social upheavals, the violence of which cannot be foreseen.

The European war has passed its first anniversary, and a year of valuable time has been wasted in debating, so that we are just now only at the beginning of our preparations for our own defense. Our medical preparedness should have begun to function immediately after our offer to the government in September, 1939. Always, muddling politics restrain patriotism. Now, at the request of the War Department in June, the American Medical Association is actively helping in military preparations.

Questionnaires have been sent to all physicians to discover how willing, how qualified, and how loyal they may be. The immediate response of more than 134,000 physicians justifies the traditional devotion of the medical profession to public service. The Committee on Preparedness is building the skeletal fabric for effective service in every state not only for active field service but for service on draft boards and for protection of civilians at home. The profession will be ready when called for.

Meanwhile there must be no relaxation of educational standards in the quality of medical care for our country of the future.

Our medical future should be viewed from high points of idealism, standing upon firm, well-established, biologic foundations. Those who wish to see the highest national health might well work for a selective draft of all our citizens to choose those who may become the parents of future Americans.

Physical fitness must be recognized as an important step toward national fitness. Fifty-two per cent of Americans are said to be physically competent for hard work. This level must be raised if our medical futures are to be viewed with satisfaction.

I believe that educators should be urged to turn their minds from sentimental to practical methods of equipping youth for the hard realities of life.

I believe that all boys and girls who are physically fit should be vigorously trained from the ages of 5 to 20 not to carry guns or to engage in military techniques but to develop strong healthy bodies that will not only be able to meet emergencies of our national life but will build sturdy competent citizens.

The athlete has been idealized to the extent that many thousands of us spend many hours of

many days exercising vicariously, sitting in stadia screaming our approval but making no effort to maintain our own general efficiency.

Annual examinations of the apparently healthy have long been advocated with very small results. Examinations of school children are carefully done in few places. I do not favor peace-time conscription for military service, but I do advocate careful annual examination of every school child and training for physical fitness throughout school life. I believe that such universal study of the school child, added to promotion of health through intelligent nutrition and sanitary housing, is a more important elemental defense than guns or planes or tanks.

While the common effort in our educational system seeks its objective in a thin veneer of so-called general culture, average abilities for the practicalities of life are neglected. Fear of regimentation seems to restrain school administrators and limits their vision or understanding of the destructive experiences of indulgent self-expression, which seems at this moment to be resulting in a disorderly generation.

Physical training of the physically fit and rehabilitation of the physically unfit are largely the lot or miss concern of undirected individuals. Every school and college in the country should be provided with serious medical consultants who in turn should be educated and inspired promoters of national health.

If every college for women or men would emulate, for the next twenty years, the physical training now carried on at West Point, we should have thousands of young people physically fit for healthy citizenship and prepared to meet emergencies at home or abroad. We should have many thousands of young people so physically fit that they would be willing to soil their white collars and their strong hands with the work of the World.

For many years we have been discussing ways and means of preparing for solution of our internal warfare between employee and employer, and still we have more than nine million unemployed. No one seems to know how many of these are physically, morally, or mentally unfit or unadjustable to possible demands for their services, but it may be safely assumed on the basis of studies of other groups that more than 30 per cent or more than three millions of them are physically unfit and many more unskilled for work that might be offered them in more prosperous seasons.

The President of the United States has said that Americans are soft. He also said that "if we are to survive we cannot be soft in a World in which there are dangers—dangers which threaten America—dangers more deadly than were those the pioneers had to face."

He also wisely said that old pioneers "put hard fiber in the American spirit and strong muscles in the American back."

The selective draft for the war of 1917 and 1918 revealed that from 30 to 40 per cent of those

examined were unfit to fight Have we Americans profited from the lessons of that experience? Statistics of June, 1940, indicate that we have not

Defects found in applicants for voluntary enlistment in the Regular Army, month of June, 1940, Second Corps Area, New York City, Colonel Magruder, Lieutenant Drummond

Dr Kopetzky thinks that our statistics will be much better in the current conscription

We are boastful of our great schools and colleges, of our greatly increased literacy, of our vast numbers of college students We have idealized the life of those in the learned professions

We have educated so many people to wear white collars that there are not enough people who are fit for the skilled mechanical work that we need so much at this time We have stimulated a false pride in the attainment of college degrees and dislocated labor by crowding some fields while others are poorly supplied We have encouraged a complacent snobbery that looks down its nose at productive labor We have forgotten to teach that healthy existence is built upon practical foundations, and we have paid so little attention to physical fitness that we shall have to draft 3,000,000 men for military service if we shall secure 2,000,000 men and probably proportionately the same number of women for the defensive jobs that can be served by women.

Our mental unfitness is illustrated by 500,000 hospital beds occupied by the institutionalized insane

Our social unfitness is illustrated by a half million active syphilitics and a half million migrating indigents—15 per cent of whom are said to have open tuberculosis This is indeed a serious indictment of American civilization

In medical education most of the current writing and thinking has been in the interest of the development of specialists. Here again practicalities are forgotten I believe a national health program would be promoted by the concentration of medical education upon developing good average physicians for average patients And I believe that the young doctor of today comes too late into the field of practical service

May I say in brief detail that I believe that much could be gained by permitting those who aspire to practice medicine to elect basic science study at the end of the second year of high school and continue a concentrated study of the sciences through two years of college, at which time they should be given a B S degree, and then go into medical schools where without a repetitious work they should be immediately introduced to a four-year course of clinical medicine

I believe that these students should be well educated in internal medicine, obstetrics and traumatology and minor surgery, in physical therapy, and in a basic knowledge of the needs of the public health

The education of interns should also be a serious drilling in practical clinical experience, and the young physician might thereby find himself in practice two or three years earlier than he is today, in his best years, when he may learn how to live and to become a useful, self-supporting independent citizen This would in no sense let down the standards of competency of the average physician to care for the average patient. It would in no sense lessen the opportunity for specialization, and specialists could and would develop themselves to attain the high standards of the specialist boards if that system of certification should continue to be thought advisable.

Medical horizons in America will not be reached until every American shall have available a good physician competent to take care of all of his ordinary physical accidents

Medical futures will not become highly illuminated unless all physicians, specialists as well as general practitioners, shall be continuously educated So long as he lives, graduate education must be carried to the doctor

The specialist is often able to go to school at frequent intervals for refresher courses or for lessons in techniques, but the general practitioner is more likely to be limited in his freedom from his practice, and graduate education for the benefit of the average patient must be a painstaking part of any national health program

Hospital facilities will grow to meet the needs of all our people, and, if the present interest in transportation prevails, good roads will run to every physical frontier In the state of New York good roads have brought every citizen within thirty minutes of a physician

Statistically, the health of the American people measures up to higher standards than are found in any other large nation, two nations only, Australia and New Zealand, have lower death rates, but these figures do not satisfy a profession that aims still higher

Postgraduate courses conducted by medical societies and organized clinical groups are not entertainments for doctors enjoying brief vacations, they are serious efforts to support the intelligent clinical knowledge of practicing physicians and to carry American medicine to higher ideals of public service.

In advocating a new health program I believe that a National Health Department with a Secretary of Health in the Cabinet is as important as a War Department with a Secretary of War

Defense against disease is as important as defense against a military enemy Defense of the nation's health is vital to all other defensive forces, but any defensive program will fail to reach its objective unless it is supported by a vigorous offensive which will arouse the public conscience

Health means so little to most people until it fails or is lost that the first emphasis is on curative therapy, second on prevention (which attracts minor attention except when given to the prevention of the communicable diseases of

children), and last and very little emphasis on the promotion of physical fitness through good nutrition, good housing, and physical training

I believe in eliminating the present confusions and duplications of Washington bureaus by centralizing national health functions, which now seems functionally possible under the leadership of the Social Security Administrator, the Honorable Paul McNutt

I believe in decentralizing the care of the sick individual by originating his care in the smallest political subdivision such as a school district, where his real condition is known, and then carrying his necessary call for help to the township, to the county, and to the state in that order, but to the National Government as infrequently as possible

The future of medicine in America is intimately involved in the evolution of our national intelligence.

Our National Government can coordinate nationwide programs and our local governments can carry them to successful accomplishment

Sickness and health are individual experiences that have community importance

Our medical futures are limited by the mental, moral, and physical fitness of every American.

Presentation of Award. Dr Kaiser concluded the proceedings with these words

"I am very happy that the last act that I am called upon to perform as president of the Monroe County Medical Society is one in which I can extend my personal appreciation to Dr Flynn and particularly to extend to him in a small way a tribute from the Medical Society of the County of Monroe

"We have already heard from members of our local group, from the state group, and from the national group There is very little I could add, and it is a matter of considerable pleasure to me to be able to present to Dr Flynn this tribute of recognition from the Medical Society of the County of Monroe It is merely a token, but it does represent our appreciation for your own accomplishment and also for the honor that you have brought to our society "

Response by Dr Flynn

"My friends This expression is not the flattery—it is the real McCoy Everyone here to-

day has sacrificed something, some more than others, so this means real friendship

"This testimonial dinner has been an enjoyable surprise I am thoroughly conscious of the fact that in honoring me you are honoring the State Medical Society and organized medicine in general. And this is as it should be, because medical organization has given us as individuals the privileges that we are accorded by the public today and the position that we hold in the community

"It is up to each and every one of us to follow closely the doctrines of organized medicine and adhere especially to the code of ethics If we do this, we will continue to be worthy of the confidence of the public

"I am deeply appreciative of the kind talks made by the speakers this evening, of the wonderful work performed by the committee on arrangements and by each and every one here present, for you all have helped to make this testimonial dinner a real success

"May I thank you wholeheartedly and wish you a pleasant good-night "

Mr Samuel B Dicker, mayor of Rochester, was then introduced

"I think I learned something by coming here tonight, because I learned how Dr Flynn addresses an audience in short, terse words If I could get away with that, I could live in peace and harmony with myself

"I am very happy to have been able to come here tonight and greet you here at this testimonial dinner to our good citizen, Dr Flynn. We in Rochester are fond of our city When one Rochesterian died and went to heaven and wanted to pass the gates, he was asked whence he came, and he said, 'From Rochester, New York.' And St Peter said, 'Well, I don't think you will like it up here.'

"We are proud of Rochester, but we are proud chiefly of the character and citizenship represented by our good friend, Dr Flynn. I have known Dr Flynn for many years, and we are very happy that Rochester has been honored to have one of its distinguished scientists and citizens selected to lead the Medical Society of the State of New York. I know that Rochester's name will go forward because of the work of Dr Flynn in this state and throughout the nation "

County News

Albany County

The county society elected the following officers on December 11: president, Dr Thomas O Gamble, of Albany, vice-president, Dr John J Phelan, of Albany, secretary, Dr Homer L Nelms, of Albany, treasurer, Dr Frances E Vosburgh, of Albany, historian, Dr Charles K. Winne, Jr., of Albany, censors, Drs Philip L Forster, Arthur J Wallingford, John B Horner, Raymond G Leddy, of Albany, and Dr John F Mosher, of Coeymans, delegates, Drs William B Cornell, of Menands, Otto A. Faust, of Albany and Raymond F Kiroher, of Albany, alter-

nates, Drs Emerson C Kelly, Charles A. Perry, and William Feltman, of Albany

Bronx County

Dr J Lewis Amster, former health commissioner and surgeon, has been appointed president of the medical board of Morrisania Hospital to succeed Dr Nathan B Van Etten, now president of the American Medical Association.

Matthew Woll, vice-president of the American Federation of Labor, addressed the county society on December 18, on the urgent necessity

of health examinations for draftees and industrial workers

Cayuga County

The annual dinner of the county society and the woman's auxiliary was held on December 19 at the Osborne Hotel in Auburn. Justice Benn Kenyon spoke on "Medicine and Law."

Chautauqua County

The county society held its annual meeting with election of officers at White Inn in Fredonia on December 18. Dr Ernest J Kelley, Jr., of Jamestown was elected president and Dr Benjamin S Custer, of Fredonia, vice-president. Dr Edgar Bieber, of Dunkirk, was re-elected secretary and Dr Frederick J Pfisterer, of Dunkirk, treasurer.

Dr J Sutton Regan, of Buffalo, gave a talk on the diagnosis and treatment of vascular diseases. Dinner followed the meeting.

Chemung County

The county society has requested that \$10,000 be included in the 1941 budget in Elmira to pay physicians for attending relief patients in the hospitals, and the City Council has deferred action to determine if other cities pay for such service.

Chenango County

At its annual winter meeting at the Norwich Club on December 10 the county society elected Dr Leslie T Kinney, of Norwich, president, Dr Ben Lee Dodge, of Bainbridge, vice-president, Dr J H Stewart, of Norwich, secretary-treasurer, and Dr Matt Boname, of Oxford, censor. Dr Stewart has served the society as secretary-treasurer for over twenty years.

Dr A K Benedict, of Sherburne, was named delegate to the State Society meeting with Dr J Mott Crumb, of South Otselic, alternate.

At the afternoon session Dr John F Kelly, of Utica, explained the "Medical and Surgical Care Plan," and a committee, composed of Drs Kinney, of Norwich, Evans, of Guilford, Stewart and G L Manley, of Norwich, was appointed to consider and report.

Dr Charles D Post, of Syracuse, presented a paper on "Nephritis," and at the joint luncheon with Norwich Rotary discussed the work of the medical profession in relation to national defense registrants.

Dutchess County

The county society met at the Amrita Club in Poughkeepsie on December 11, and Dr Walter D Ludlum, Jr, New York City, gave a paper on "Recognition and Treatment of Hernia."

Erie County

The county society elected the following officers at the annual meeting on December 16: president, Dr Nelson W Strohman, first vice-president, Dr Harvey P Hoffman, second vice-president, Dr Harold F R Brown, secretary, Dr Louise W Beamis-Hood, treasurer, Dr Roy L Scott, all of Buffalo. Elected to the Board of Censors are Drs Joseph D Godfrey, Buffalo, Elmer T McGroder, Buffalo, Warren S Smith, Kenmore, Roswell K Brown, Buffalo, and Charles W Bethune, Buffalo.

Dr Herbert E Wells in his address as retiring president deplored the influence of politics in the defeat of the society's welfare medical plan by the board of supervisors. He said "Our main object in urging the plan, even with its inadequate provisions for reimbursing physicians in Buffalo for home-call service, was the establishment of the principle enabling the indigent sick to call their own physicians."

Fulton County

The county society held its annual Christmas dinner on December 18 at the Hotel Johnstown. There were forty-two members and their wives present.

Herkimer County

The county society will remit dues of any member who enters military service, it was decided at the annual meeting at the Mohawk Valley Country Club on December 10, when Dr H Dan Vickers, Little Falls, was elected president to succeed Dr George Frank, of Frankfort. Dr Frank discussed socialized medicine in his address as retiring president.

The organization voted to complete furnishing the medical society room in the County Historical Building, provided under the will of Dr A. Walter Suiter.

Other officers elected were: first vice-president, Dr B G Shults, Herkimer, second vice-president, Dr N D Lill, Dolgeville, third vice-president, Dr D F Aloisio, Herkimer, secretary, Dr Fred C Sabin, Little Falls, treasurer, Dr A L Fagan, Herkimer, librarian, Dr G S Eveleth, Little Falls, censors, Drs G A Burgin, Little Falls, Harold F Buckbee, Dolgeville, James F Gallo, Herkimer, H J Sheffield, Frankfort, and Dr F S Conterman, Ilion.

Dr Burgin was named delegate to the State Society meeting, with Dr Shults as alternate.

County physicians should have a voice in the selection of the doctor for county welfare work, Dr F H Moore, retiring president of the Herkimer Academy of Medicine, declared in his address at the academy session in the Palmer House on December 17. At the scientific session, Dr B G Shults read a paper on "Complications of Diabetes," with discussion led by Dr Robert Dennis, who also showed films on traumatic injury.

Kings County

The topics and speakers at the scientific session of the county society on December 17 were "Current Concepts of the Nature of Rheumatic Fever," by Dr Irving Graef, and "Management of Rheumatic Infection," by Dr Cary Eggleston, both of New York City.

The friends of Dr Maurice J Dattelbaum, the incoming president of the county society, are arranging a dinner in his honor to be held January 28, at the Towers Hotel, 7 30 p m. Tickets are \$4.00 per person and may be obtained from Dr Abraham Koplowitz, 1401 President Street, or from the committee. Make checks payable to Dinner Committee.

The forty-second annual meeting of the Associated Physicians of Long Island will be held in Brooklyn on January 25. The scientific session

will be at St Catherine's Hospital. The program will be provided by the staff. In the morning there will be clinics. The members of the Association will be guests of the hospital at luncheon. At 2 00 P. M. a number of brief papers will be presented followed by the usual interesting discussion. At the executive session, immediately following, election of members and officers for 1941 will take place.

The annual dinner will be held at 6 30 P. M. at the Hotel Bossert and it will be a steak dinner, tickets, \$3 50. An interesting and entertaining after-dinner speaker will be provided by the Entertainment Committee.

Dr Alex Louria succeeds Dr Charles Goldman as president of the Williamsburg Medical Society. He was elected on December 9 at the thirty-fourth annual meeting held in the Leon Louria Memorial Auditorium of the Jewish Hospital.

Elected to serve with Dr Louria were Dr David A. Meiselas, first vice-president, Dr Abraham Ravich, second vice-president, and Dr Bernard Seligman, secretary-treasurer.

Dr Jack London was elected president of the South Brooklyn Medical Society at a meeting at the Baltic Street Health Center, on December 14. Other officers elected were Dr Charles Bastable, vice-president, and Dr Julius Schlein, treasurer.

The society is participating with the Department of Health, the Kings County Medical Society, and the Brooklyn Tuberculosis and Health Association in a drive to check tuberculosis in South Brooklyn, Red Hook, and Gowanus.

Dr Daniel A. McAteer, president of the county society, was one of the principal speakers at the dedication of the new five-story Fort Greene Health Center and Brooklyn Borough office of the Department of Health on December 19 in the auditorium of the new building at Flatbush Avenue Ext. and Fleet and Willoughby streets.

Livingston County

The annual meeting of the county society was held on December 12, at the Hotel Dansville, and officers were elected as follows: president, Dr Kenneth T. Rowe, Dansville, vice-president, Dr Alden J. Townsend, Dansville, secretary-treasurer, Dr Gerald E. Murphy, Mt. Morris, delegate, Dr Charles Gullo, Mt. Morris, alternate, Dr Gerald E. Murphy, Mt. Morris, censors, Drs Gerald B. Manley, Geneseo, Harold F. Hulbert, Dansville, Wm. T. Shanahan, Son-Yea, Gerald E. Murphy, Mt. Morris, and Charles L. Newton, Geneseo.

Dr George M. Doolittle of Craig Colony, Son-Yea, retiring president, gave an interesting and instructive paper on "Convulsive Disorders."

Montgomery County

The annual dinner meeting of the county society was held December 11 at the Elks Club in Amsterdam. The retiring president, Dr S. L. Homrighouse, expressed his thanks to the members for their cooperation during the year and stated that death had removed two of the most prominent members of the society whose names would not soon be forgotten, Dr Charles Stover and Dr H. M. Hicks, and that the society suffered another irreparable loss in the recent death of Dr Clark E. Congdon, of Fort Plain.

The annual election of officers resulted as follows: president, Dr Julius Schiller, vice-president, Dr James M. Bernhard, secretary, Dr Roger Conant, and treasurer, Dr Leonard M. McGuigan.

Dr E. H. Ormsby was elected delegate to the State Society and Dr J. A. Dickson delegate to the Fourth District Branch. Dr W. H. Seward was re-elected censor.

Nassau County

In an effort to give high-school students more knowledge about cancer, the Nassau County Cancer Committee has been conducting educational work in the secondary schools of the county. It is hoped that thereby these students will have a much more sensible attitude toward cancer and not the fear that the present generation has of this disease. Secondly, a few cases of cancer have been discovered as a result of these talks when students have spoken to parents or relatives urging them to seek medical attention for a condition that has existed too long or been neglected.

New York County

The program at the meeting of the county society on December 23 was as follows: (1) "Medical Preparedness in the Navy," by Captain Earl C. White, Medical Corps, U. S. Navy, by invitation, and (2) "The Medical Department of the Expanded Army," by Colonel Frank W. Weed, Medical Corps, United States Army, by invitation. They were discussed by Colonel Samuel J. Kopetzky, Medical Reserve Corps, U. S. Army.

Niagara County

At the annual meeting of the county society on December 10 the following officers were elected: president, Dr Raymond S. Barry, Niagara Falls, vice-president, Dr Forrest W. Barry, Lockport, secretary, Dr Charles M. Dake, Niagara Falls, treasurer, Dr Dudley B. Fitzgerald, Lockport, delegates to State Convention, Drs Guy S. Philbrick and Richard H. Sherwood, Niagara Falls, alternates, Drs Robert P. Reagan, North Tonawanda, and Harley U. Cramer, Lockport, censors, Drs Robert R. B. Fitzgerald, Lockport, Roy H. Wixson, Niagara Falls, and Emil T. Mueller, North Tonawanda.

Oneida County

The speaker at the meeting of the county society on December 19 in Hotel Utica was Dr Alfred W. Adson, of the Mayo Clinic, Rochester, Minnesota. He read a paper on "Sympathectomy as a Therapeutic Measure." The subject was discussed by Dr Frederick F. Wetherell, of Syracuse.

Sharing the speaking program was Dr T. Wood Clarke, who spoke on "The Allergic Abdomen." Dr R. E. Vandever, of Rome, discussed the topic.

Onondaga County

An institute on radiology will be held at the Syracuse University College of Medicine on Saturday, January 18, presented under the auspices of the Central New York Roentgen Ray Society, the Medical Society of the State of New York, Syracuse University College of Medicine.

and the Division of Cancer Control of the New York State Department of Health

Speakers at the afternoon session will include Dr Albert Lenz, president, Central New York Roentgen Ray Society, Dr James M Flynn, president, Medical Society of the State of New York, Dr Herman G Weiskotten, dean, Syracuse University College of Medicine, Edith H Qumby, Sc D, associate physicist, Memorial Hospital, New York City, Dr Merrill C Sosman, roentgenologist, Peter Bent Brigham Hospital, Boston, Dr Ursus V Portmann, radiation therapist, Cleveland Clinic, Cleveland, Dr Fred W Stewart, pathologist, Memorial Hospital, New York City, Dr Stafford L Warren, chief radiologist, Strong Memorial Hospital, Rochester, New York, Dr Louis C Kress, director, Division of Cancer Control, New York State Department of Health

The speaker at the dinner meeting in the evening at the Hotel Syracuse will be Dr R. R. Spencer, assistant chief, National Cancer Institute, United States Public Health Service

Under sponsorship of the county society, twenty-five Onondaga County physicians, who are medical examiners of Selective Service Board met in December, to request that draft board examiners be paid on the same basis as the civilian physicians attached to induction boards

Draft board examiners work without fee, giving their services Properly to examine a registrant requires about one-half hour, and with fifty draftees to be called early in January, physicians who are attached to draft boards find their own schedules interfered with, especially as there are usually more men to be examined, by one-third than the quota to be provided from the district

Onondaga County physicians will ask a fee of \$1 00 per draftee, which is \$2 00 an hour, or about \$15 a day at that rate

In a number of districts in the state, examining physicians have been reported as resigning because the draft work interfered with their private practice

Orange County

Dr Ross Schmitt, Middletown, was elected president of the county society at a meeting in the Palatine Hotel in Newburgh on December 10

Other new officers are vice-president, Dr George Dempsey, Cornwall, secretary-treasurer, Dr E C Waterbury, Newburgh, delegate to State Society, Dr M D Stivers, Middletown, delegate to First District Branch, Dr W J Hicks, Middletown

A portrait of Dr David R. Arnell, one of the founders of the American Medical Society in 1806 and its president from 1809-1811, was presented to the organization by Dr C E Townsend, of Newburgh

Otsego County

At the annual meeting of the county society on December 11, the following officers were elected president, Dr Charles C McCoy, Cooperstown, vice-president, Dr Frederick B Devitt, Oneonta, secretary, Dr Edmund H Kerper, Oneonta, treasurer, Dr Frederick E Bolt, Worcester, censor, Dr Earle C Winsor, Schenectady, delegate, Dr James Greenough, Oneonta, and alternate delegate, Dr Edwin P Hall, Oneonta.

Rensselaer County

The following officers were elected by the county society on December 10 president, Dr John O Sibbald, vice-president, Dr Alson J Hull, secretary, Dr Elizabeth Palmer, and treasurer, Dr Francis J Fagan, all of Troy The censors are Dr William Trotter, Troy, and Dr Charles H Sproat, Valley Falls, delegates, Drs Stephen H Curtis and John D Carroll, both of Troy, and alternates, Drs Clement J Handron and George F Reed, both of Troy

The officers were installed at the annual banquet of the society at the Hendrick Hudson Hotel on December 11 Dr Alan R. Moritz, professor of legal medicine at the Harvard Medical School, spoke on medicolegal jurisprudence, and Dr Peter Irving, executive secretary of the State Society, discussed society activities and spoke on the need for increasing the number of physicians serving in connection with local draft boards in view of the anticipated increase in the work load in the coming months

Richmond County

At the annual meeting of the county society on December 11, the following officers were re-elected president, Dr Herbert A Cochrane, New Brighton, vice-president, Dr H Lynn Halbert, Tompkinsville, secretary, Dr George W McCormick, Port Richmond, treasurer, Dr Curtis J Becker, St George, and censors Dr Frederick Coonley, St George, Dr Andrew J McGowan, New Brighton, Dr Nathanael Fedde, Annadale

St. Lawrence County

Dr Charles Dean Landlaw, of Canton, who died on December 13, at the age of 62, was a past-president of the county society

Schenectady County

The county society met at the Mohawk Golf Club on December 12 and elected the following officers president, Dr Charles E Wiedenman, vice-president, Dr Jos H Cornell, treasurer, Dr Raymond H Warner, secretary, Dr Gomer Richards, and censors, Drs Arnaldo A. Samorini, D Glen Smith, William F Nealon, all of Schenectady Dr Sullivan was elected to the house of delegates of the State Society The alternate is Dr Charles Rourke Delegate to the Fourth District Branch is Dr Beverly Vosburgh, and the alternate is Dr C L Moravec

Seneca County

The new officers of the county society are as follows president, Dr Arthur F Baldwin, Waterloo, vice-president, Dr Floyd W Hoffman, Romulus (Dr Hoffman has been called for military service), secretary-treasurer, Dr Duane B Walker, Waterloo, delegate to the State Society, Dr Arthur F Baldwin, and delegate to the Seventh District Branch, Dr Joseph E Allen, Seneca Falls

Tompkins County

Dr Dean F Smiley was elected president of the county society at the annual meeting at the home of Dr Esther Parker near Jacksonville on December 16

Other officers elected were vice-president, Dr Henry W Ferris, secretary-treasurer, Dr

Willets Wilson, and censors, Drs Richmond Douglass, Arthur B Berresford, Leo P Larkin, Henry B Sutton, and Henry E Merriam.

Approximately seventy physicians and their wives attended the meeting and a dinner at the Jacksonville Methodist Church which preceded it

Romeyn Berry, of Jacksonville, columnist for *The Ithaca Journal*, gave a talk at the meeting, and Cornell football pictures were shown by Mose Quinn, freshman coach at Cornell.

Yates County

The annual meeting of the county society was held at the Benham Hotel in Penn Yan on December 12. The following officers were elected for the coming year: Dr A. S. Jones, Dundee, president, Dr W. G. Roberts, Penn Yan, vice-president, and Dr R. F. Lewis, Penn Yan, secretary and treasurer.

The society unanimously passed resolutions to protect the interests of physicians called to national service.

Robert P Wadhams	61	Univ & Bell	December 16	Manhattan

SERVING ON COMMITTEES

Serving on a committee of a county medical society is a task which should be taken seriously or the appointment not accepted at all, says an editorial in the *Milwaukee Times* which is being widely quoted in the medical press. This premise takes for granted that the committee appointed has something to do and has not been created merely to give some physicians an assignment.

Each committee member is under an obligation to serve faithfully and contribute something of real worth to his organization. Many do not realize this and are perfectly willing to let one or two members on the committee do all the planning and the work that is necessary. Are you that kind of a committeeman?

It might be interesting to consider the ideal member of a committee. What are his qualifications and how does he meet his responsibilities?

First, he should have the interest of the medical profession at heart. This may seem a platitude, however, the physician who fulfills this qualification is rarer than is generally thought, for he must often submerge his personal feelings to aid in the accomplishment of what is best for the profession.

Second, he will give thought and study to the subjects which come up before the committee and will not just be one of those present. It is surprising how few people will assume responsibility or feel it their obligation to do more than is absolutely demanded of them. No committee can do much on behalf of the profession which is not made up of members who are genuinely interested in the tasks to which they have been assigned and are willing to give the time necessary to put through the plans they have evolved.

Third, he will make it a point to be on hand

for all meetings unless his professional duties require him elsewhere. So many physicians accept committee appointments and fail to attend. These are often practitioners who for some time have felt that they deserve appointment to a committee.

Nothing is so demoralizing to a committee as to have two or three out of ten or fifteen members present. There is no quorum, therefore, no action can be taken. Those on hand become discouraged and unless interest is somehow stimulated they also drop out and the committee becomes dormant.

Fourth, he will not allow one or two members to assume entire burden for developing plans but will contribute ideas of his own. It is easy to find fault and not contribute oneself. Unless the physician has worthwhile contributions to make to the committee, he should not serve on one. This does not mean that he must be in agreement with other members of the committee, but when a thorough discussion has been held the majority opinion should rule and he should subscribe to it.

Fifth, he will do what he can to contribute toward an orderly and not overlong meeting. Many committee members take up time with unnecessarily long discussions of unimportant details or, if the subject is of importance, too much time discussing it. Nothing is so discouraging to a committee as long and tiresome sessions.

Committees can do much to improve the efficiency of medical societies because most of the planning is in their hands. Their personnel, however, should be carefully selected from among those men who will meet the qualifications here described. Only then can they justify their existence.

INSTITUTE ON RADIOLOGY
Syracuse University College of Medicine
Syracuse, New York

Saturday, January 18, 1941

Presented under the auspices of Central New York Roentgen Ray Society; Medical Society of the State of New York, Syracuse University College of Medicine, Division of Cancer Control of the New York State Department of Health

PROGRAM

January 18, 1941

Syracuse University College of Medicine, Syracuse

Meeting called to order at 1 30 p m by

Albert Lenz, M D, President

Central New York Roentgen Ray Society

Opening Remarks

James M Flynn, M D, President

Medical Society of the State of New York

Chairman of the Meeting

Herman G Weiskotten, M D, Dean

Syracuse University College of Medicine

- 1 45 p m "Physics of Radiation for the Radiologist"
Edith H Quimby, Sc D, Associate Physicist
Memorial Hospital, New York City
- 2 30 p m "Roentgenological Aspects of Brain Tumors, Diagnosis and Treatment"
Merrill C Sosman, M D, Roentgenologist
Peter Bent Brigham Hospital, Boston, Mass
- 3 15 p m "Indications and Results of Roentgen Therapy"
Ursus V Portmann, M D, Radiation Therapist
Cleveland Clinic, Cleveland, Ohio
- 4 00 p m "Radiosensitivity of Tumors"
Fred W Stewart, M D, Pathologist
Memorial Hospital, New York City
- 4 45 p m "The Cyclotron"
Stafford L. Warren, M D, Chief Radiologist
Strong Memorial Hospital, Rochester, New York
- Discussion conducted by Louis C Kress, M D, Director Division of Cancer Control,
New York State Department of Health

DINNER MEETING (Informal)

7 00 p m Small Ballroom, Hotel Syracuse, Syracuse, New York

Toastmaster—James M Flynn, M D

Introduction of Speaker by

Edward S Godfrey, Jr, M D, Commissioner

New York State Department of Health

Speaker

R R Spencer, M D, Assistant Chief, National Cancer Institute, United States Public Health Service

Local Committee on Arrangements

Carlton F Potter, M D, Chairman

Donald S Childs, M D, Lucas S Henry, M D, Foster C Rulison, M D

While the Institute is planned especially for radiologists, all physicians in the state are cordially invited to attend. The price of the dinner is \$2 00 No other fees will be charged The sponsoring agencies are very anxious to know how many plan to attend the afternoon session and how many will be at the dinner Reservations should be addressed to

O W H Mitchell, M D, Chairman

Council Committee on Public Health and Education

Medical Society of the State of New York

428 Greenwood Place, Syracuse, New York

Woman's Auxiliary

To the Medical Society of the State of New York

AS CHAIRMAN of the State Organization I should like to emphasize the need of every doctor's wife in the state becoming a member. No organization can do its best work unless there is a complete membership, each member shouldering her part. Even with a little over one-third of the state organized there has been a great deal accomplished in public health education and in promoting a greater feeling of unity and responsibility. In the already organized counties the medical societies find the auxiliaries have helped a great deal in many ways. With the splendid work now being done, the help of the unorganized counties is needed in order that even more and better things may be accomplished in the future—Florence M. Johnson, chairman of the State Organization (Mrs. R. F.)

County News

Cayuga. The regular monthly meeting of the auxiliary was held at the Auburn City Hospital Nurses' Home. Dr. Frederick Beck, of Biggs Memorial Hospital, was the guest speaker. A social hour was enjoyed by those present.

Fulton County. Twenty-four members of the auxiliary met December 17 at the home of Mrs. H. C. Hageman, Highland Terrace, and enjoyed a Christmas party. A report on work done for the Red Cross was given by Mrs. H. B. Riggs. Members did work for Bundles for Britain. Miss Dorothea Ehle entertained with piano numbers and gifts were exchanged. Mrs. Claude Bledsoe and Mrs. Everett Perkins assisted the hostess.

Jefferson County. The auxiliary held a dinner meeting at the Black River Valley Club on December 12. After the dinner sewing for the Red Cross was done. Several members are heading committees and helping at Red Cross Headquarters. For January it is hoped to have a speaker talk on National Medical Preparedness and to have the superintendent of a local hospital explain the hospital situation in case of any emergency. There is a large military training camp near Watertown which will have a military hospital. The auxiliary will no doubt find valuable work to be done.

Kings County. The auxiliary held its annual meeting December 10 at the Medical Society Building. Mrs. Milton B. Bergman presided. The program was a motion-picture program produced by the American Airlines and a talk by an American Airline hostess. Following the election Mrs. John L. Bauer, organizing president, installed the incoming officers. Those elected were Mrs. Louis Harris, president, Mrs. A. F. R. Andersen, 1st vice-president, Mrs. Robert Rogers, 2nd vice-president, Mrs. Clifton Dance, secretary, Mrs. Allen Hull, associate secretary, Mrs. Henry Benfield, treasurer, Mrs. Julian Rose, assistant treasurer, and Mrs. Robert Barber and Mrs. Milton Bergman, directors for three years. Mrs. Bergman as outgoing president was presented with a past-president pin and a gift from the auxiliary by Mrs. Bauer. Tea was served by the hospitality

chairman, Mrs. Valentine Bourke, and her committee.

Madison County. Mrs. Martin Melamed, of Oneida County, writes: "Our program for the winter will be a get-together dinner and social evening. A main topic—The Children of Oneida and What They Do—will be discussed, and a different phase of the topic will be viewed at the following meetings."

Nassau County. The annual Christmas program was a delight to the busy wives of the Nassau county physicians. Projects related to public health and medicine were laid aside for the evening while games, directed by Mrs. Lola A. North, and Christmas carol singing, led by Mrs. W. J. Lee, of Garden City, pleased all the members of the auxiliary. Mrs. M. R. Bowles, chairman of the entertainment committee, invited the more than one hundred women present to draw their gifts from beneath the Christmas tree. Refreshments were served from an elaborately decorated holiday table. Six new members were added to the roster of the organization.

Onondaga County. The November meeting of the auxiliary was held at the Crouse-Irving Educational Building. Mrs. Marion S. Dooley and Dr. John J. Buettner were the guest speakers. The members of the Herkimer County Woman's Auxiliary were invited to attend this meeting, but they were unable to come, presumably because it was election eve. The December meeting of the auxiliary was the annual meeting and was preceded by a luncheon held at the Hotel Syracuse Terrace Room. Guest speakers were Mrs. Luther H. Kice, of Garden City, Long Island, president of the Woman's Auxiliary to the Medical Society of the State of New York, and Dr. Brewster C. Doust, president of the Onondaga County Medical Society. Reports of the various committees were read and the slate of the nominating committee was presented by Mrs. John J. Buettner.

Mrs. Edgar M. Neptune was unanimously re-elected president. All other elections were also unanimous as follows: 1st vice-president, Mrs. W. W. Street, 2nd vice-president, Mrs. Carl E. Muench, treasurer, Mrs. Raymond J. Pieri, assistant treasurer, Mrs. Gerald C. Cooney, recording secretary, Mrs. Brooks W. McCuen, corresponding secretary, Mrs. Donald E. Moore, assistant corresponding secretary, Mrs. John J. Hogan, directors for three-year term, Mrs. H. O. Brust and Mrs. Joseph R. Wiseman, delegates to the annual convention, Mesdames Garfallo, Street, Lavine, Andrews, Elwood, Hitchcock, Ritter, alternate delegates, Mesdames Swift, Lewis, Menzies, Myron, Paul, Chambers, Rosenberger, and public relations chairman, Mrs. Frederick N. Marty.

Orange County. Mrs. H. F. Murray, of Port Jervis, was elected president at the annual meeting held December 10 at The Maples. Other new officers are: president-elect, Mrs. W. W. Davis, of Chester, vice-president, Mrs. Leo DuBois, of Beacon, recording secretary

Mrs N P Cosco, of Middletown, treasurer, Mrs M W Walton, of New Hampton Speakers for the afternoon were Mrs Luther Kice and Dr T W Neumann, of Central Valley Mrs Kice talked on the concentrated aims of an auxiliary toward public education in matters of medicine and hygiene Dr Neumann urged the organization to continue its active interest and real assistance in public health forums, stating that "the public has a right to know what the finest standards of the physicians are" He complimented the part played by the group in its widespread educational program

Rensselaer County Mrs John J Rainey was elected president of the auxiliary at the annual meeting at the McKean Staff House of the Leonard Hospital Other officers are Mrs Eugene F Connally, president-elect, Mrs P L Harvie, 1st vice-president, Mrs W H McShane, 2nd vice-president, Mrs L S Weinstein, recording secretary, Mrs F T Cavanaugh, corresponding secretary, Mrs N F Brignola, treasurer, Mesdames J H Donnelly, S H Curtis, A W Benson, V C Jacobsen, directors

The new officers will be installed at the February meeting Mrs S H Curtis, retiring president, conducted this meeting during which all committee chairmen gave their reports. A Christmas party was held after this meeting

Mrs Helmer P Howd was chairman of the committee that distributed gifts to children in the hospital Instead of the usual Christmas donation of toys, money was given for the purchase of lamps for the nursery at the Leonard Hospital At the recent board meeting a sum of money was donated to the Red Cross and to the Home for Indigent Physicians.

Schenectady County The Executive Board of the auxiliary entertained on December 27 for seventy members at the home of Mrs. F Leslie Sullivan, Sunnyside Road, Scotia The guests were received by Mrs A W Greene, Mrs W Mallia, Mrs H W Galster, and Mrs. E MacD Stanton During the afternoon Mrs. Philip Parillo gave piano selections and Christmas carols were sung under the direction of Mrs Frank Furlong

NOW FOR THE MALINGERER

The difference between a lingering illness and a malingering illness is that the malingering kind has a miraculous recovery right after the masquerader has been excused from military service An outbreak or epidemic of malingering is now expected, and some words of wisdom are printed in the *J A M A* to guide medical examiners who have to meet it

Men sometimes have their teeth extracted to avoid military service, others shoot or cut off fingers or toes or put their hands under cars for this purpose These, of course, do not miraculously recover after the medical examination, but real injuries may be exaggerated, and crutches, paraded at the examination, be discarded next day

We are told that malingerers may be divided into three general groups

(a) Real malingerers with nothing the matter with them, who injure themselves, who make allegations respecting diseases or such condition as drug taking, or who simulate disease with full consciousness and responsibility—all for the purpose of evading military service Many of these will have been coached

(b) The psychoneurotics, who are natural complainers and try to get out of every disagreeable thing in life, perhaps only partially conscious of the nature of the seriousness of what they do and only partly responsible In many the motives are not persistent and many can be made into good soldiers

(c) Confirmed psychoneurotic individuals with long history of nervous breakdowns and illnesses who behave like group (a) above but more persistently and from whom not much can be expected in the way of reconstruction.

As to feigned medical diseases

(a) The detection and management of

malingerers simulating medical diseases depend on the absence of positive signs of an individual who presents the general characteristics of the malingeringer There is especial need for the physical examination to be thorough in this group Some of the cardiac cases at first regarded as malingering may later be found to be mitral stenosis or bacterial endocarditis Similarly, proper tests may show the existence of peptic ulcers in those suspected of feigning digestive abnormalities The estimation of the reality of rheumatic pains is always a difficult matter

(b) Tachycardia and thyrotoxicosis may be temporarily induced by ingestion of drugs, such as thyroid extract Egg albumen or sugar may be added to urine Undiluted canned milk may be made to simulate the urethral discharge Cantharides may be taken to cause albuminuria. Digitalis and strophanthus may be taken to cause abnormal heart action The skin may be irritated by various substances Cathartics may be taken to bring about purging or to simulate a chronic diarrhea. An appearance of hemoptysis may be produced by adding blood, either human or that of animals, to the sputum. Sometimes merely coloring matter is added. Those who can vomit voluntarily what they swallow use the same means to create the appearance of hematemesis Similarly, coloring matter may be added to the stools Mechanical and chemical irritants are made use of to cause inflammation about practically all the body orifices. Jaundice may be simulated by taking picric acid Crutches, spectacles, trusses, and strappings are made use of to create the appearance of disability Artificial jaundice is recognized by demonstration of picric acid in the urine

The semiannual meeting of the Women's Medical Society of New York State will be held at the New York Infirmary for Women and Children, on January 25 at 9 30 A.M. A dinner will be held at the Cosmopolitan Club at 7 00 P.M.

The annual meeting of the New York Heart Association was held January 7 at The New York Academy of Medicine Dr Ernst P Boas, president of the Association, presided at the meeting

THE NEW 5 mg. BENZEDRINE SULFATE TABLET

Brand of Amphetamine Sulfate

There has been a persistent demand by physicians for a smaller Benzedrine Sulfate Tablet—in addition to the present 10 mg. size.

Your druggist now stocks these two sizes

5 mg.

BENZEDRINE SULFATE TABLETS (SINGLE-GROOVED)

Particularly appropriate in depressive states and other conditions for which a small dosage unit is desired

10 mg.

BENZEDRINE SULFATE TABLETS (CROSS-GROOVED)

For use in narcolepsy, post-encephalitic parkinsonism, alcoholism and other conditions for which a large dosage unit is required

IMPORTANT! In prescribing Benzedrine Sulfate Tablets, please be sure to specify the tablet-size desired—either 5 mg or 10 mg.

ITH, KLINE & FRENCH LABORATORIES, PHILADELPHIA, PA.

Lend Us 14 by 22 Inches of Desk Space—

...and you can see for yourself what a valuable addition to your diagnostic facilities the G-E Model F-3 Portable X-Ray Unit could be. Right in your own office you can operate this powerful, efficient, compact x-ray unit exactly as it will be used in your practice—on your desk or table.

The satisfactory experience of hundreds of F-3 owners is your assurance that you can rely on the F-3 for dependable performance—in your office or at the patient's bedside—wherever adequate roentgenological service is not available. Its simplified control is easy to operate, and its full flexibility provides accurate alignment with minimum patient discomfort.

If, like most value-wise medical men, you demand proof of what your money will buy before you spend it, you won't accept mere claims about the worth of any portable x-ray unit. G-E willingly offers to furnish full proof of the F-3 unit's reliability, dependability, and economy of first cost and maintenance. Protect your investment; buy the safe way—sign and mail the coupon to see the proof!

CLIP, SIGN, and MAIL

- ☐ Have your local representative arrange with me for a "See-the-Proof" demonstration of the G-E Model F-3 in my office, at my convenience.
- ☐ Send me my copy of the G-E Model F-3 Catalog.

Asthma and the General Practitioner By James Adam, M D Octavo of 157 pages Baltimore, Williams & Wilkins Co, 1939 Cloth \$2 00

In a small volume of 150 pages written especially for the general practitioner, the author discusses his methods of treatment of bronchial asthma On the basis of his experiences with 2,000 patients the writer is convinced that asthma is largely preventable and not incurable Although admitting the existence of food and inhalent allergy in some cases, the majority of patients were successfully treated by general methods

Increased carbohydrate intake, vitamin-deficient diet, complex modern life, and defective adrenal function, all combine to react on the autonomic nervous system, the endocrines and enzyme action to create a "toxic soil on which allergy seeds"

The author's general treatment consists of some form of physical exercise to avoid nasal congestion, breathing exercises, a vitamin-rich and low-carbohydrate diet to help enzyme ac-

reaction of the system in question. This biologic reaction is given on the basis of the quantum theory to determine allergy, general resistance, specific resistance, especially as to tuberculosis, intensity of disease, extensity of active foci, and immunity. The reading of the attractive and excellently reproduced graphs is probably far beyond the mathematic capacity of the average physician, but that does not justify the statement that the medical profession is still in the "Classic ancient times" of Aristotle and Virchow.

MAX BERLINER

Practical Bedside Diagnosis and Treatment. By Henry Joachim, M D. Quarto of 828 pages. Springfield, Charles C Thomas, 1940. Cloth, \$7.50.

Because of the great amount of information that has been amassed concerning the diagnosis and treatment of disease, the attempt to put all this together in one volume becomes a formidable task. The author has attempted this bravely and has produced a book that is concise and readable and that demonstrates thorough knowledge of bedside diagnosis and treatment. Unfortunately the effort to accomplish all this in some eight hundred pages has required a brevity that impairs the usefulness of the book. The discussion of the diagnosis of a given disease reads like a rapid summary. This effect is enhanced by the continued use of short sentences. When the reader looks for advice as to treatment he is again disappointed by brevity. For example, one-half page is devoted to the serum treatment of pneumonia. The reviewer was sorry to discover that the author adheres to the old anatomic classification in the section on diseases of the heart. There are sections on simple endocarditis, aortic insufficiency, mitral stenosis, etc., which will be confusing to the modern student who has been taught the etiologic classification.

The shortcomings of the book are due to the attempt to cover a tremendous amount of ground in a short space, and as a result it does not do justice to the knowledge and experience of the author.

E P MAYNARD, JR.

The Newer Nutrition in Pediatric Practice. By I Newton Kugelmass, M D. Octavo of 1,155 pages, illustrated. Philadelphia, J B Lippincott Co, 1940. Cloth, \$10.

The purpose of the book is "An understanding of the normal functions of the body in relation to each of the fifty essential nutrients is the only basis for individualizing nutrition at all ages, types of constitution, and levels of body functioning." Section one on nutritional physiology reveals the physical and chemical basis of the growing organism in terms of the materials of life derived from food, air, and water. Section two on nutrition in health presents established principles and procedures for the advancement of positive health and the prevention of chronic disease. Section three on nutrition in disease considers most of the disorders of infancy and childhood in terms of nutrient causation or involvement as a basis for rational therapy.

The book has 183 illustrations with 422 tables, a full index, and abundant listing of modern literature. With its 1,155 pages it makes its initial bow among the illustrious books on nutri-

tion and naturally assumes its place as a reference work on nutrition and the child.

The nomenclature and so-called "facts" are up to date, and in some places one wonders whether the new is any advantage over the old. However, "It has had, wisely or unwisely, the assistance or criticism of no one, having grown like practice, out of typical cases 'animo et fide'."

ARCHIBALD D SMITH

Compendium of Regional Diagnosis in Lesions of the Brain and Spinal Cord. A Concise Introduction to the Principles of Localization of Diseases and Injuries of the Nervous System. By Robert Bing. Translated and edited by Webb Haymaker. Eleventh edition. Quarto of 292 pages, illustrated. St Louis, C V Mosby Co, 1940. Cloth, \$5.00.

This publication, the eleventh version since its publication in 1909, continues to maintain its high place in the esteem of all students. Because of the complexity of its anatomy the study of neurology is viewed with apprehension by the beginner, and firm pegs are essential on which to hang the clothing of ideas. This book provides such pegs thus assuring a well-grounded approach to the study of clinical neurology. The student is grateful for the unusual clarity of style as well as dogmatic fashion in presentation. When crowded shelves are cleared of books, a volume of Bing remains as testimony of the esteem in which it is held.

In the 275 pages of reading matter are found 125 illustrations, 27 in color, most of which can be found in the earlier editions and form an essential basis of the charm which this volume holds for all students who have learned their early clinical approach from its pages. The reviewer continues to have for this book the same high regard formed twenty years ago.

HAROLD R. MERWARTH

Medical Diseases of War. By Sir Arthur Hurst, M A. Octavo of 327 pages. Baltimore, Williams & Wilkins Co, 1940. Cloth, \$5.50.

The vast experience of the author and the access he has had to medical records of the various armies during the time elapsed from the second edition in 1918 to the present has enabled him to give an excellent work.

A different point of view, contrasting war situations with civil neuroses, is presented. Civil practice enjoys Freudian orthodox analysis with abreaction of repressed unconscious material lasting years. The author's material is situational and entirely conversive, hysterical syndromes, fear, injury, and concussion being direct precipitating factors.

True "shell-shock" is defined, his constitutional timid type or martial misfit is his war neuroses candidate.

Symptomatology, be it contractures, paralysis, seizures, special sense disorders, may be dangerously perpetuated if regarded entirely in an organic light. Suggestion by false sympathy, use of term "shell-shock," prolonged bed rest, and indiscriminate physical therapy all spell chronic invalidism.

Immediate psychotherapy including explanation, persuasion, and manipulation within forty-eight hours is the keynote. Diffusing an atmosphere of cure insures speedy excellent results.

THE MAPLES, Inc , Rockville Centre, L I

An exclusive rest for invalids convalescents and chronic cases. Also post-operative, special diets and body building cases. Efficient day and night nursing.

GOLD PHARMACAL CO , New York

Say you saw it in the NEW YORK STATE JOURNAL OF MEDICINE

The chapter on skin diseases is an excellent guide for the medical officer with troops whether in war or peace

The chapter on gas poisons appears somewhat casual when the varied pathologies and the enormous high casualty rate caused by them are considered

In bringing this work up to date, the author and his collaborators have given us a useful and timely treatise on military medicine

CARL W LUPO

Tuberculosis of Bone and Joint. By G R Girdlestone, M A Octavo of 265 pages, illustrated New York, Oxford University Press, 1940 Cloth, \$8 75

This volume contains a wealth of knowledge on tuberculosis of bone and joints The author discusses the subject excellently from the standpoint of local and general manifestations and covers very well tuberculosis of hip, spine, knee, sacro-iliac, ankle, tarsus, shoulder, elbow, and wrist

His chapter on Pott's paraplegia is enlightening and is worthy of perusal by both the general practitioner and the orthopedic specialist

Illustrations of x-rays and the diagrammatic illustrations of pathology, together with illustrations of operative procedures, all add to the merit of this work

Apparatus is discussed to some extent throughout the text and also in the appendix

HERBERT C FETT

Dermatologic Allergy An Introduction in the Form of a Series of Lectures By Marion B Sulzberger, M D Octavo of 540 pages, illustrated Springfield, Charles C Thomas, 1940 Cloth, \$8 50

To those of us in dermatology who are familiar with Dr Sulzberger's profound knowledge of this subject and his wide experience, this volume comes as a rare treat Despite his modest assertion in his preface that "this book is intended to be only a primer, an Introduction to Dermatologic Allergy in the form of lectures based on those I have been giving to beginners," it is certain to enjoy a wide popularity because it places in the hands of the profession one of the most comprehensive expositions of the subject of allergy in relation to the skin that we have as yet had the pleasure to examine The author has the happy faculty of lucid expression, and the idea of publishing his work in the form of lectures, greatly augmented with many notes and lavishly illustrated with some thirteen color plates and many excellent photographs, is a happy one The reader, if he will but take each lecture in its proper turn, is certain to gain a full and entirely authoritative knowledge of the subject

NATHAN THOMAS BEERS

Elmer and Rose Physical Diagnosis Revised by Harry Walker, M D Eighth edition. Octavo of 792 pages, illustrated St Louis, C V Mosby Co, 1940 Cloth, \$8 75

The eighth edition of Elmer and Rose has been revised by Harry Walker of the Medical College of Virginia There have been a few changes in the text since the last edition, with some rearrangement of the chapters, but the greatest revision has been in the illustrations These and the numerous diagrams are pertinent, well re-

produced, and constitute perhaps the most valuable feature of an excellent text Mention should be made of the use of the new tinted paper in this edition The reviewer found it definitely more restful and easier to read both in natural and artificial light

MILTON PLOTZ

A Textbook of Medicine By American Authors Edited by Russell L Cecil, M D Fifth edition Octavo of 1,744 pages, illustrated. Philadelphia, W B Saunders Co, 1940 Cloth, \$9 50

No greater compliment can be paid a textbook than the necessity for a revised edition every three years That has been the history of this book since the first edition in 1927 This edition revised and entirely reset presents a few additional commendable features Ten entirely new articles have been added, and thirty others rewritten One hundred thirty-one added illustrations further adorn the text

The chapter on lobar pneumonia, of course, had to be rewritten in the light of the introduction of chemotherapy The discussion of this phase of the treatment is complete and up to date

The student of the past generation notes with amazement that the discussion of rheumatoid arthritis receives as much space as typhoid fever

The volume consists of 1,744 pages The reviewer again urges the publishing of the ever-increasing bulkiness of the modern textbook of medicine into two volumes The book fully deserves the increasing popularity it enjoys

S R BLATTES

The Injured Back and Its Treatment. Edited by John D Ellis, M D Quarto of 377 pages, illustrated. Springfield, Charles C Thomas, 1940 Cloth, \$5 50

This book is a series of monographs by different individuals Various phases of the subject are discussed so that the reader may obtain a bird's-eye view of this ever-present complaint

The chapter on "Man's Posture and Backache A Symptom of Visceral Disease" serves as a background for the book

The routine examination of the injured back is thoroughly discussed. The management of recent compression fractures of the vertebral bodies without cord injury is comprehensive Early reduction with adequate fixation until healing occurs is the criteria of good treatment. All of the various methods of obtaining complete hyperextension are described

The chapters on the neurosurgical aspects of back injuries and the role of the articular facets in low back pain are instructive

Disabling back injuries frequently originate from trivial trauma due to associated pathology Prevention of back injuries by teaching the proper method of lifting and fitting the type of individual to his job is needed

This book is a compact review of different aspects in the diagnosis and treatment of the injured back. It is a "must" for the library of the general practitioner and specialist Each chapter contains an extensive bibliography for reference The diagrams and x-ray illustrations are well done

Editorial

Industrial Health and the Defense Program

The sessions of the Third Annual Congress on Industrial Health, recently concluded in Chicago under the auspices of the Council on Industrial Health of the American Medical Association, shed much cold, searching light upon the problems of industrial health and the deficiency of current facilities for meeting them.

A critical analysis of the data presented seemed to indicate a great lack in the recent past of intelligent, coordinated integration between industry on the one hand and administrative education on the other. The net result seems to be that industry has attempted, in solving its safety problems, to enter the educational field in an effort to create practically trained personnel, while educational institutions have confined themselves largely to inquiry along the line of pure research. While these several activities have undoubtedly produced some results, they have left unfilled enormous gaps, due to the disjointed and apparently little coordinated schedules. These gaps become the more apparent as the speed-up of industry progresses in the production of defense materials. Shortages begin to appear in nursing and other technically trained personnel, an inadequate number of physicians apparently are familiar with the techniques of industrial preventive medicine and industrial disease diagnosis, labor shortages are creating problems in the employment of the physically handicapped, the aging of the popula-

tion is becoming increasingly a problem of industrial health.

Always important, the health and well-being of industrial workers becomes doubly significant to the national interest in times of world political imbalance, when the national safety is threatened both within and without. To provide a maximum of health and physical efficiency four agencies are involved: industrial management, education, government, and medicine. The Council on Industrial Health has done a most commendable service in bringing these four agencies together in this Congress—toward a mutual understanding of the common problems to be met.

The industrial speed-up is making acute the many shortages in trained personnel. Surveys of small shops and industries by the government reveal the considerable hazards from dusts, chemicals, solvents, etc., which are there encountered. More than mere consultation about these hazards and the deficiency of personnel is necessary. Something has to be done about it. Who is to do it? How is it to be done? Who is to pay for it? Is such a program to be left to the individual states to meet as they think fit, or should such a program be organized and supervised by the Federal government through such an agency, for example, as the Social Security Administration? To say how it should be done is not in our province. A project

requiring the coordination of such diverse activities as those of medicine, nursing, engineering, materials production, administration, chemistry, architecture and many others should be integrated into the general defense program by some agency which is in a position to know what the defense program contemplates

Industrial hygiene in the State of New York is under the supervision of the State Department of Labor and has been the outgrowth of a campaign mainly for the prevention of industrial accidents. At the present time the Department carries on through its Division of Industrial Hygiene many investigations of factory conditions, dust analyses, examinations of ventilating systems

and the like. We feel sure that the State Department of Labor would cooperate, as would the State Department of Health and many other government agencies, in evolving a plan by which the last of our questions could be answered, namely how such an expanded program of instruction in industrial hygiene could be financed. For financed it must be. There is little use speaking practically, in drawing elaborate plans or developing projects before the question of how they are to be paid for and by whom is settled. If the industrial health program is to become an effective measure for national defense it must be coordinated with the general plan and be adequately financed without loss of time.

"Tuberculosis Must Go"

The new program to eradicate tuberculosis in the State of New York, outside of New York City, received added impetus early in January at a meeting of leading state officials, executives, and representatives of the Medical Society of the State of New York and voluntary health and welfare agencies. The meeting was the first one of a special coordinating committee appointed by Commissioner Edward S. Godfrey to initiate an expanded case-finding and control program during 1941.

Representing the State Department of Health were Commissioner Godfrey, Dr. Robert E. Plunkett, Dr. V. A. Van Volkenburgh, and Miss Marion Sheahan, the State Department of Mental Hygiene, Commissioner William J. Tiffany, the State Department of Social Welfare, Commissioner David C. Adie, the State Charities Aid Association's Committee on Tuberculosis and Public Health, Mr. Homer Folks, Mr. George Nelbach, Mr. Robert W. Osborn, the Medical Society of the State of New York, Dr. Peter Irving, secretary, the Metropolitan Life Insurance Company, Dr. Donald Armstrong, third vice president.

Elimination of tuberculosis as an im-

portant medical and social problem within twenty-five years or an even shorter period was seen as a possibility by Dr. Godfrey, if to its control were applied the knowledge gained by past experience and if specific measures for its prevention were made the dominant factor in dealing with tuberculosis as the infectious disease. It is discovery at the earliest moment of the advanced cases which spread infection and bringing them under control. To this end Mr. Folks announced a grant of \$5,000 from the Metropolitan Life Insurance Company to help finance the participation of the S. C. A. A. in the tuberculosis eradication project during 1941. The Association's total tuberculosis budget is \$61,000. In 1907 the tuberculosis mortality rate, said Mr. Folks, was 152.8 per 100,000, in 1939, it had declined to 36.4.

The program for 1941 as outlined by Dr. Plunkett would be directed toward a much greater concentration of effort upon examination of contacts, x-ray examination of persons presenting symptoms of fatigue, loss of weight, persistent coughs, or other unexplained symptoms, case finding among groups particularly susceptible because of occupations, racial, age, social, or economic factors, more

prompt and effective utilization of hospital facilities. Participating in the program will be the various public health authorities, sanitariums, tuberculosis clinics, public health nursing services, tuberculosis associations, and other health and welfare agencies.

The active participation of the Medical Society of the State of New York and of its various component county societies in such a program of public health education as that advocated by the coordinating committee is assured. Such a program of case finding and the elimination of sources of occupational as well as off-duty tuberculosis contacts fits appropriately into the contemplated national effort to eliminate health hazards in industry and civil life. It seems to meet the requirements in that it will be competently directed and adequately financed.

Tuberculosis Abstracts*

SIXTEEN and one-half million men have registered for military service. Almost one million of them have thus far been selected. According to news reports the men will be subjected to a hardening process to the point where they will be able to march thirty miles per day bearing full equipment. It is highly important that among them there shall be none who, because of a tuberculous focus, will crack under the strain. So that costly lessons, learned during the World War may not go unheeded, Spillman in an article in the *Journal of the American Medical Association* summarizes the methods employed to discover tuberculosis, calculates the enormous cost of service-acquired tuberculosis and discusses what should be done to safeguard the nation's manpower and financial resources against the enemy which bores from within.

Tuberculosis and Military Service

How can the recruit who already has active tuberculosis be recognized, that he may be rejected for the protection of himself and others?

The World War is 22 years behind us, yet the Federal government pays in compensation for tuberculosis that originated in service about \$3,000,000 each month. Analysis of voluminous

and complicated Federal reports dealing with service-acquired tuberculosis yields the following approximate figures

Cost of vocational training	\$129,000,000
Insurance	130,000,000
Compensation	600,000,000
Hospital care	100,000,000
	<hr/> \$959,000,000

The total number of men compensated for tuberculosis in 1922 (it is not feasible, from the annual reports, to run the figures back past 1922) was 36,600. In 1939, the total number was 55,634, including 1,947 deaths for that year.

The cost of taking a man who has tuberculosis into the service cannot be accurately calculated because of many factors that are still unknown and costs that are not apparent, but the author estimates that the figure would be somewhere around \$10,000 per man to date, certainly not less than \$7,500, to which should be added at least \$50 a month for the rest of the man's life and compensation for his dependents after death.

Study of army procedure during the World War leads to the conclusion that the methods employed for the detection of tuberculosis were inadequate. This does not detract from the stature of that distinguished army surgeon, Colonel George E. Bushnell, the advisor to the Surgeon General on all matters pertaining to tuberculosis. It was the consensus of experts in 1917 that adult exogenous infection with tuberculosis is rare, that infection in childhood is well nigh universal and that every infection confers an immunity to anything short of massive doses of bacilli in later life. By the same token, adult tuberculosis was held to result from a reactivation of the antecedent infection. It was thought that for every soldier who had incurred tuberculosis as a result of military service, 10 others had brought the disease with them into the army. Present-day experience does not uphold this belief—to cite at random just one of numerous communications, Diehl and Myers prove the development of 6 cases of tuberculosis in one college fraternity a year after one of its members was found to have a positive sputum, and the development of tuberculosis in a girl several years after her sorority roommate was found to have tuberculosis.

Colonel Bushnell trained a large number of highly competent diagnosticians, to whom he imparted the significance of the post-tussal moist rale and the technic of eliciting it. The patient is instructed to cough gently at the end of deep expiration. When he inhales after the cough the rale is heard. The presence of persistent moist rales was the criterion for determining the existence of tuberculosis. Several prominent physicians and radiologists tried to induce the Surgeon General to make the radiograph the decisive factor in the diagnosis of pulmonary tuberculosis. The practical difficulties in the way of the adoption of the radiograph were, however, insuperable, according to Colonel Bushnell, in which conviction he was supported by a special committee of the Council of National Defense which investigated the question. Among the difficulties were the enormous cost of photographing, the impossibility of obtaining a sufficient number of plates (made of glass and most of it imported from Belgium) and the lack of trained radiologists.

*Reprinted from *Tuberculosis Abstracts* 14, No 1 (Jan.) 1941.

Draft boards set up in every community, added to the difficulty. These boards included local physicians who were supposed to reject draftees with disqualifying defects. While most draft boards functioned honestly and intelligently there is evidence in official publications that, far from weeding out the manifestly tuberculous, some boards actually concentrated tuberculosis at some of the camps, thinking that they would benefit by change of climate and by army life. In the re-examination of 19,827 men at Camp Kearny, for example, 853 cases of tuberculosis (4.33 per cent) were discovered.

With this background, what should our procedure be in the present situation? Of the available methods for the mass diagnosis of tuberculosis among recruits, physical examination and radiography need to be considered on a basis of relative merits. Evidence of the inadequacy of physical examination to detect tuberculosis is overwhelming. The last word so far as the army was concerned in 1917 was that "the only trustworthy sign of activity of apical tuberculosis is the presence of persistent moist rales." In the light of present-day knowledge this sign is worth only about 12.5 per cent. In spite of the acknowledged skill of the army examiners of 1917 only about one-eighth of the actually existing clinically significant tuberculosis was detected.

The radiograph should be the criterion in weeding out tuberculosis in today's mobilization. In what form? Fluoroscopy gives no record and is highly subjective. As demonstrated by the experience of a large life insurance company, fluoroscopy in skillful hands may serve as an alternative to a prohibitively expensive routine of roentgenography, but even this company has, since 1936, been making routine roentgeno-

grams of the chest of every applicant for employment.

The paper roentgenogram is speedy and convenient and cheaper than celluloid. Radiologists as a whole do not favor the paper radiogram while tuberculosis workers are enthusiastic over it. If celluloid films were available on rolls like the paper rolls they would undoubtedly be preferred. Paper roentgenograms are vastly preferred to no roentgenograms but celluloid would be preferred if the author were given a choice.

Photography of the fluoroscopic screen is another possibility. But if this method, known as fluorography, is no more than 90 per cent efficient as compared with the standard celluloid roentgenogram, as the author believes, the 10 per cent shortage in diagnosis would cost a great deal of money in compensation later. Fluorography is today a highly promising method but awaits further improvements before it can compete with celluloid roentgenograms.

For radiography there are many kinds of apparatus varying in price and capacity. What is most important, however, is the skill and knowledge of the operator.

The author's final conclusion is

"A normal chest roentgenogram should be the criterion of acceptance in a future mobilization, including the proposed draft for training, and it should be made and reported before the recruit has spent a night away from his own roof to obviate a repetition of the claims for aggravation of pre-existing tuberculosis which occurred during and after the World War."

The Value of Radiography in Detecting Tuberculosis in Recruits, Ramsay Spillman, M.D., J.A.M.A., Vol 115, No 16, October 19 1940

Early Diagnosis of Cardiac Syphilis

The importance of the campaign to eradicate syphilis by early and intensive treatment is epitomized by the statement of Berk,¹ in this issue of the JOURNAL, that "unsuspected or insufficiently treated syphilis may manifest itself as a cardiac disease. Once clinically recognizable, it frequently baffles all treatment. The patient becomes a hopeless invalid and often dies without warning." The vast amount of clinicopathologic data anent cardiovascular lues has added but little to the early detection of involvement of the heart, its valves and musculature and the ramifications of its arterial system. Electrocardiographic studies have received only passing attention, and those recorded in the literature have dealt mainly with the changes noted in advanced lesions.

Berk's study, over a period of nine years, of 172 cases of cardiovascular syphilis showed that of the 20 in their earliest stages, wherein clinical evidence was highly equivocal and where the electrocardiograms showed abnormal deviations in only 5 per cent, the graduated exercise test altered this figure to 25 per cent. Before the exertion test in 7 cases of aortic insufficiency, 5 were normal electrocardiographically. Following exercise, however, marked pathologic changes were noted. In 2 cases, the ST₁ and ST₂ were negative and the ST₃ positive, in 2 others, the ST₂ and ST₃ were negative, while in the remaining one, the ST₃ alone was negative. All of these showed in addition numerous extra systoles from ectopic foci. It is Berk's opinion that an objective diagnosis of early cardiovascular syphilis is

¹ Berk, L. H. *N Y State J Med*, this issue.

possible by electrocardiographic studies made with the graduated exercise tests. Where 95 per cent of these cases exhibited normal findings with the usual method of examination, transient myocardial anoxemias and pathologic cardiographs were demonstrable in 25 per cent of the cases examined on recordings taken at intervals of from two to ten minutes after effort. A positive test is indicated by a characteristic upward or downward displacement of the RS-T junction and alterations of this segment in two or more

leads. Ectopic beats and changes in the initial deflection were also present.

That a normal or borderline electrocardiogram in a case of syphilitic aortitis with beginning ostial stenosis can become positive after the exercise tests is an observation of note. If his studies are confirmed, the routine use of this procedure in the follow-up of luetics under treatment may unearth cardiovascular syphilis at a much earlier stage than is possible at the present time.

Educational Offensive

The importance of the early diagnosis and thorough treatment of syphilis cannot be overemphasized. Especially at this time it is of the utmost importance in view of the increasing number of young men entering military service. For this reason we devote this issue of the JOURNAL to a symposium on syphilis as our contribution to the educational offensive being conducted by the Surgeon General.

Surgeon General Thomas Parran, in a letter to State Health Officers, announces plans to acquaint every man registering under the Selective Service and Training Act with the facts about syphilis and gonorrhea and their relation to national defense, and he urges

that registrants have blood tests for syphilis.

"Registrants for America's first peacetime draft," Dr Parran pointed out, "make up the age group in which is concentrated most cases of infectious syphilis. Blood tests of this group will lead to the discovery of a large number of cases of syphilis in the stage of the disease during which treatment is most effective. Stopping the spread of syphilis among this group would bring the control of syphilis among the whole population nearer by many years."

"Discovery and treatment of syphilis among registrants *now* will increase the reservoir of men available for active and efficient duty in the armed forces and in industry."

Work in a British Clearing Station

With our defense program under way and with little else to help us except our experiences in the last war and probably some scant reports that have filtered through from the Spanish civil war, the brief notation of Brown, Dennison, Ross, and Divine,¹ on their experiences at a clearing station in Britain during the evacuation from Dunkirk, affords us a guide for the activity of the Medical Corps in this new type of warfare.

Within a space of twenty-four hours, 500 seriously wounded men, exhausted by lack of sleep, food, and constant bombardment, were admitted to this receiving station. Copious drinks of hot tea cut down the number of intravenous infusions which otherwise would

have been necessary. Prolonged treatment for shock, with the aid of cradles, transfusions, morphine, and synthetic adrenal hormones saved many lives. Surgical cases were divided into immediate, early, and late. In the first category were included head wounds, perforating abdominal wounds, severe burns, and thoracic injuries. Following the evacuation of these cases, fractures, removal of foreign bodies, and cases requiring colostomy received attention.

Amputations and cases of gangrene then followed. The therapy here was irrigation with peroxide of hydrogen, local application of sulfapyridine, and the administration of the drug orally. Their report, that the closed plaster technic for treating infected wounds proved more simple and efficacious than the

¹ Brown J. M., Dennison, W. M., Ross J. A. and Divine, D. *Lancet* 239: 443 (1940).

old method of irrigation with Carrel-Dakin solution, is notable and bears out our current reports

It appears that the only problem that presented difficulties at this casualty clearing station was that of anesthesia. Due to the severe shock and exsanguination which these

soldiers exhibited, the deepest stages were reached with a minimum amount of anesthetic. That this small British hospital could treat successfully 500 wounded under the most adverse conditions within a period of twenty-four hours is a tribute to the resource of the medical profession.

Correspondence

NEW YORK STATE REREGISTRATION FOR PHYSICIANS IN MILITARY SERVICE

Attention of all concerned is called to the following correspondence, which is self-explanatory.

MEDICAL SOCIETY OF THE STATE OF NEW YORK, 292 MADISON AVENUE, NEW YORK

December 28, 1940

Mr Charles B Heisler, Director
Division of Professional Education
University of the State of New York
State Education Department
Albany, New York

Re Reregistration of Physicians Called into
Uniformed Service

Dear Mr Heisler

A question has just been asked me that I was unable to answer, and I would be very much obliged if you would let me have an official ruling that will cover the matter. A doctor in practice in this city who went into service in the middle of

December expects to be in uniform throughout 1941, and, therefore, absent from practice. Does the law require that he reregister for 1941, or can he legally omit reregistration and payment of the \$2.00 fee until he returns to practice?

I presume many such questions will come to this office from now on. It is in my mind that we could be helpful both to your office and to the doctors if we had on record a definite ruling from whatever source that should come.

If you would think well, I would be very glad, in addition, to publish an announcement in the NEW YORK STATE JOURNAL OF MEDICINE.

Sincerely yours,

Peter Irving, M D, *Secretary*

THE UNIVERSITY OF THE STATE OF NEW YORK

THE STATE EDUCATION DEPARTMENT

ALBANY

January 3, 1941

Dr Peter Irving, *Secretary*
Medical Society of the State of New York
292 Madison Avenue
New York, New York

Dear Dr Irving

I am glad to give you a ruling on the question raised in your letter of December 28.

The law prescribes that every physician actually engaged in the practice of medicine under the laws of this state must register with the Department each year. This means that any physician so engaged in practice during any part of the year 1941 must register, even though he may be otherwise engaged for the greater part of the year.

On the other hand a physician not so engaged during the whole of the year 1941, whether by

reason of military service or for some other cause, is not required to register although he may do so, if he wishes, in order that his name may appear in the printed list. The failure to register by such a physician in no way affects the validity of his license.

Therefore, a physician who was engaged in practice in this state on January 1, 1941, must register, even though he expects to enter military service within the month or later and a physician who was not engaged in practice in this state on January 1, 1941, is not required to register until he resumed his former status and again takes up the practice of medicine in this state later in 1941 or thereafter.

You are quite at liberty to give this letter such publicity as you may wish.

Very truly yours,

Charles B Heisler, *Director*

CARDIOVASCULAR SYPHILIS

A Clinical and Electrocardiographic Study

L H BERE, M D , New York City

SINCE statistics show a decline in syphilis, the incidence of cardiovascular syphilis will probably diminish in the future. At present, however, cardiovascular syphilis remains a menace to public health and presents a problem to the cardiologist in spite of more efficient control and better treatment of early syphilis. The next twenty-five years will demonstrate the effectiveness of early, persistent, and continuous treatment of syphilis in the prevention of cardiovascular disease.

The present study was undertaken in an attempt to ascertain the accuracy and significance of the electrocardiographic findings and to observe any correlation that might exist between the clinical aspects of the disease and the pathologic picture.

After an insidious and long latency lasting from five to twenty years, unsuspected or insufficiently treated syphilis may manifest itself as a cardiac disease. Once it is clinically recognizable it frequently baffles all treatment. The patient, having missed the opportunity for successful early treatment, becomes a hopeless invalid and often dies without warning.

Pathology

The recognition of mesaortitis as a late syphilitic condition and of its pathologic, anatomic, and microscopic structure has become well known only since the beginning of this century.¹⁻⁵⁻¹²

Four types of cardiovascular syphilis can be differentiated. The supravulvar, uncomplicated aortitis represents the earliest localization of the disease. In this type the pathologic process may extend gradually up to the aortic arch and the descending aorta where it ends sharply at the border between the descending and thoracic aorta, the ascending process may involve the commissures and the aortic valves, producing an insufficiency of the aortic valves but never invading the other cardiac valves. One or both coronary ostia, lying in the sinus of Valsalva, may become narrowed or completely closed as the inflammatory process reaches them, thus producing a coronary ostial stenosis.

On gross examination the aortic walls are found thickened, and the inner surfaces of the intima, due to the inflammatory changes in the media, show a peculiar wrinkling and buckling. The muscular and elastic fibers in the media are more or less destroyed and replaced by fibrous tissue which may dilate in a diffuse or circumscribed way and lead to aneurysm. Media and adventitia show extensive inflammatory changes, in the latter mainly about the vasa vasorum. Arteriosclerotic changes with fatty degeneration and calcification are often superimposed on the syphilitic fibrous changes of the intima.

Clinical Course

According to the localization and extent of the anatomic changes in the aorta and in the heart, the clinical picture will vary as to diagnosis and prognosis.³⁻¹⁴⁻¹⁹⁻²⁰ The pathologic process may show a progressive tendency or may become nonprogressive at any time.

The nonprogressive form of uncomplicated aortitis probably comprises most of the cases that have had early specific treatment and systematic follow-up or have, because of other biologic factors still unknown, reached the latent stage. It is not usually recognized clinically and is quite often an accidental finding at autopsy.

The diagnosis of the progressive as well as the nonprogressive form of uncomplicated aortitis in the large majority of cases shows certain characteristic symptoms and signs that make reasonably certain the diagnosis of syphilitic aortitis. In the early diagnosis of aortitis there is found a palpable, parasternal, diastolic pulsation in the second intercostal space, corresponding with the second aortic sound, a soft systolic murmur, audible over the aortic area, and a loud, ringing, second aortic sound. The x-ray examination will often show marked widening with increased density and pulsation of the ascending aorta, the arch, or the descending aorta. In uncomplicated aortitis the heart is often of normal size and configuration. Normal or even low blood pressure is frequently found.

Aortalgia with substernal burning and oppression, especially on exertion, emotional stress, or after meals, with diminished physi-

From Bellevue Hospital (Columbia University) First Medical Division. Dr. I. O. Woodruff, director, and the Department of Laboratories. Dr. D. Symmers, director.

cal efficiency may be an early sign. Typical or atypical anginal pain or anxiety appear later. These can be due to the uncomplicated aortitis alone. Only frequent and grave stenocardia and cardiac insufficiency point with some probability to the involvement of the coronary ostiums.

The syphilitic angina pectoris of effort (work or excitement) has an anatomic basis in the majority of cases in an organic narrowing or closure of one or both coronary ostiums. Whereas in coronary sclerosis the entire course of the coronary vessels is involved by the pathologic changes, in syphilis these changes are localized to the coronary ostiums in the sinus of Valsalva, with or without having previously involved the aortic valves.

This narrowing of the coronary ostiums occurs in about one-half of the cases. It produces a diminished blood supply to the cardiac muscle with typical complaints, after physical or emotional stress, radiating in the usual manner, and it is often relieved at once by nitroglycerin. Cases that do not show this pattern occur frequently. As proved by autopsy, there may even be a marked stenosis that never produces attacks of angina during life.

In some cases great anxiety is felt by the patient, with or without anginal pain. It occurs first after effort and later during rest without visible cause and can be abolished by nitroglycerin. This state of great anxiety, quite unexplainable to the patient, is perhaps the result of an insufficient blood supply to the myocardium.

Diagnosis of coronary ostial stenosis can often be made when a more or less grave coronary insufficiency occurs, either as a temporary or permanent state. In other cases a suddenly occurring, grave angina without apparent cause or paroxysmal nocturnal dyspnea in an apparently healthy person points to circulatory disturbances in the coronaries, death often occurring without any signal. Syphilitic aortic disease is the most common cause of sudden death.

Syphilis is important but limited in comparison with other etiologic causes underlying the true anginal syndrome, and in the past its part has been exaggerated. Including both certain and doubtful cases the proportion of persons suffering from syphilis amounts to about 20 per cent among 1,900 cases of angina collected by Gallavardin.⁴ He observes its maximum occurrences in the ages between 30 and 45. After 50 years of age the common atherosclerotic type of involvement of

the entire coronary trunk on a latent syphilitic basis prevails. The majority of cases present angina of effort, frequently with attacks at rest or at night which are indistinguishable from those associated with coronary atherosclerosis. Though not absolute, the surest sign of syphilitic angina is the presence of aortic insufficiency, usually of very slight degree. In hypertension, especially in advanced age, a very slight and sometimes intermittent diastolic murmur of aortic insufficiency has a purely functional significance.

Sudden death occurs in a great number of cases following anginal attacks—more seldom following left ventricular insufficiency with pulmonary edema or heart failure. Massive and localized infarction of the myocardium is consistently absent. The diagnosis of syphilitic aortic disease is greatly facilitated by complications involving the rest of the heart due to narrowing of the coronary ostiums in the sinus of Valsalva or to progression of the condition to the aortic valve. Unless there is a coexistent aortic aneurysm, there is not a single sign by itself characteristic of the syphilitic origin of aortic insufficiency, but rather the total of the following signs will establish the diagnosis: a rough blowing diastolic murmur with fremitus, often preceded by functional systolic murmur at the base and followed by a tambour-like, accentuated, second aortic sound. The x-ray shows an enlarged aorta and some degree of cardiac enlargement. The arteries are hard and tortuous, and a Corrigan pulse is present. The age of predilection is from 35 to 40. There is an absence of rheumatic history, and a syphilitic history can be obtained in about half the cases, with a primary infection from fifteen to twenty years previously. The Wassermann is positive in about 75 per cent.

In many of the cases showing aortic insufficiency there is an Austin Flint murmur at the apex, that is, a functional mitral mid-diastolic rumble with or without presystolic accentuation. The presence of a murmur of this character, and especially of a diastolic thrill at the apex when the aortic insufficiency is but slight to moderate, should cause one to suspect the presence of rheumatic heart disease with mitral stenosis, even though syphilis of the aorta is the correct diagnosis. In other cases an intensive to-and-fro murmur over the aortic area or left sternal border is strongly suggestive of aortic insufficiency. Without the presence of clinical signs of aortic stenosis or mitral disease, the diagnosis of pure aortic insufficiency is often

easily made in the adult, in about one-third of the cases, however, this is difficult or even impossible

The narrowing of the coronary ostia occurring in about half the cases of aortitis causes a more or less grave, coronary insufficiency as a permanent state with attacks of angina and cardiac asthma, the latter invariably being a bad prognostic sign

As the syphilitic affection of the aorta is a slow and gradually spreading process, the coronary arteries, by developing a collateral circulation, are able in spite of their narrowing to provide adequate nourishment for the heart muscle. The collateral circulation is established by the other unaffected or less damaged coronary artery and the vessels of the thorax and pericardium. For this reason we can find at autopsy considerable stenosis of one or both coronary ostia, following few subjective complaints and without previous attacks of angina

On the other hand, angina alone cannot be considered a proof of the involvement of a coronary ostium, for because of the absence of the normal function of the sclerosing aorta it occurs even in uncomplicated aortitis

Although the most common etiologic factor in uncomplicated aortic valvulitis is syphilis, this specific lesion is practically never associated with a deposition of calcium in the valves such as is seen in calcific aortic valvulitis. The clinical signs and manifestations of aortic insufficiency may be due to an acute or subacute bacterial invasion of the valves, or to acute pericarditis, or calcific aortic valvulitis, as well as being due to syphilis. In other words, there is not a single sign by itself characteristic of aortic insufficiency unless there is a coexistence of an aortic aneurysm. Cardiac pain, heart failure, and syncope occur later in the life cycle of the disease. The correct diagnosis of calcific aortic valvulitis may be made, even if the physical signs of aortic stenosis are indefinite, by careful roentgenographic examination. The presence of hypertension attributes to the difficulties in diagnosing syphilitic heart disease, since all signs attributed to the aortitis or aortic insufficiency can be explained by the elevated blood pressure

Once congestive heart failure supervenes, the course of the disease takes a progressive downward trend (in contradistinction to mitral disease), where the patient can have repeated attacks of congestive heart disease, recover, and be compensated for long periods

At present, besides inadequate specific treatment, heavy physical strain seems to be recognized as contributing to the clinical manifestations of cardiovascular syphilis. For instance, in heavy workers the statistics show an incidence of 13.5 per cent of cardiovascular syphilis, whereas in light trades it amounts to only 5 per cent. The great incidence of involvement of the circulatory system in Negroes and its appearance among them ten years earlier than in the white patient are probably due to the same physical strain on the diseased aorta

The knowledge of the electrocardiographic changes in cardiovascular syphilis is rather small compared with the great amount of clinical data accumulated. Most authors, furthermore, deal with the marked electrocardiographic changes in advanced cases or give the whole electrocardiographic problem only minor attention.^{2,5,7} Few authors stress the electrocardiogram in the early stage and especially after the exercise test is made.^{7,15,21,22} The significance of the electrocardiographic findings in cardiovascular syphilis are presented in the following analysis of our cases

Analysis of Cases

At Bellevue Hospital (Columbia University), First Medical Division, there were admitted to the wards and to the cardiac clinic from 1932 to 1940, 172 cases of cardiovascular syphilis. For purposes of analysis we have divided this number into three groups

Group 1 consists of 35 cases that were autopsied. Group 2 consists of 117 cases of advanced cardiovascular syphilis which were not autopsied. Group 3 consists of 20 cases of early cardiovascular syphilis which are still being followed. This last group was subjected to an electrocardiographic study after the graduated exercise test with most gratifying results

Group 1.—In the first group there were 32 men and 3 women. Of these, 26 were white and 9 were Negroes, their ages ranged from 29 to 65 years. In this group we found 31 cases of aortic insufficiency, 5 cases of aneurysm (2 of these associated with aortic insufficiency), and 1 case of uncomplicated aortitis. Six cases of aortic insufficiency were found in conjunction with acute coronary thrombosis with myocardial infarction

Most of the patients were admitted with congestive heart failure of short duration. The majority had syphilitic history. Most patients had no specific treatment at all, and a few had insufficient treatment. All had a

positive Wassermann Only 15.7 per cent were complicated by hypertension The causes of death were 3, acute lobar pneumonia, 2 uremia, 1, cerebral hemorrhage, 1 brain tumor, 1 portal cirrhosis with ascites, and the remainder, congestive heart failure Nine died suddenly

We were impressed by the frequency of narrowing or closure of one or both coronary ostia This occurred in 26 cases (74 per cent), 12 of which were bilateral In 9 cases the coronary ostia remained free When only one coronary ostium was involved, it was invariably the right one Only in 1 case was the left coronary ostium involved A young man, aged 33, was admitted with marked cardiac pain and died suddenly after a week His electrocardiogram showed inverted T_1 , T_2 , and depressed ST_1 , ST_2 Necropsy showed the mouth of the left coronary artery to be extremely narrow, with aortitis The heart was not enlarged

In another patient, aged 43, with slight aortic insufficiency and aneurysm of the transverse portion of the aorta, the electrocardiogram was normal He had an involvement of the central nervous system which masked the real cause of death—frontal lobe tumor The necropsy here again showed a normal-sized heart and open coronaries

Six cases in this group revealed, besides narrowing of the coronary ostia, coronary thrombosis of the anterior descending branch of the left coronary artery Every case except the 2 mentioned above showed a widened aorta and some degree of cardiac enlargement

Serial electrocardiographic studies revealed marked pathologic changes It is of interest that in 26 cases of coronary ostial stenosis 25 were associated with an abnormal electrocardiogram All cases in this group revealed left axis deviation with inverted T_1 or T_2 and T_3 The T wave was inverted, isoelectric or diphasic in lead I (14 cases), in leads II and III (2 cases), or in leads I and II together (20 cases)

Heimann⁶ refers to a notching of the ascending segment of the QRS complex which he found in 30 per cent of the cases, and he considered this sign as characteristic of syphilis Juster and Pardee,⁷ in their series of 50 cases of syphilitic heart disease, found only 7 cases showing the notch of Heimann's illustration In our series such notching of the ascending segment was found seven times only

A prominent Q_2 was present in 5 cases (14.3

per cent) While sometimes present in the absence of heart disease, Q_2 is frequently associated with myocardial damage When in addition to an abnormally prominent Q_2 there was an inversion of T_2 and T_3 with upright T_1 (1 case) or an inversion of T_1 and T_2 , the incidence of coronary ostial stenosis or coronary thrombosis was 100 per cent (4 cases)

In this series 8 cases were encountered where a downward deflection in lead III was preceded by a small upright R and followed by an upright R' (triphasic complex) Four of these were among those cases associated with coronary thrombosis, 3 had coronary ostial stenosis, and 1 had open coronaries

Nearly all cases showed definite variations of the RS-T junction and modification of the RS-T segment The upward or downward displacement of the RS-T junction as found in these cases may develop without any modification of the T wave as a whole However, if with left axis deviation a marked depression of ST_1 and ST_2 is followed by a negative T_1 or T_2 and T_3 or if ST is depressed in all three leads, it indicates grave myocardial damage (6 cases) A more pronounced cardiac enlargement is associated with negative T_1 and T_2

With all these changes, a widening of the QRS is frequently seen, and the prognosis becomes poor as the breadth of QRS increases Thus, the duration of the QRS complex is a matter of considerable importance in the significance of the electrocardiogram belonging to this group of intraventricular block (10 cases) An increase in the duration of the QRS was associated with congestive heart failure in 4 cases Four cases showed ventricular extrasystoles The numbers are too small to allow an opinion as to the prognostic significance of this type of electrocardiogram in cases of coronary ostial stenosis alone, but so far as they go they do not appear to be associated with conditions involving the coronary arteries

In order to better evaluate the electrocardiogram in patients with coronary ostial stenosis and patients with open coronaries, a detailed analysis follows

In the 26 cases with coronary narrowing or closure of one or both coronary ostia, 23 cases revealed left axis deviation with inverted T_1 and T_2 Slight or moderate depression of the ST segment in one or two leads occurred in 20 cases Five cases revealed a flat T_1 or diphasic T_1 besides left axis deviation There was low voltage of the QRS in all three leads

TABLE 1—A COMPARATIVE STUDY OF THE ELECTROCARDIOGRAPHIC FINDINGS IN 172 CASES OF CARDIOVASCULAR SYPHILIS DIVIDED INTO EARLY CASES (20) WITH EXERCISE TEST, ADVANCED CASES (117), AND NECROPSIED CASES (35)

	Early Cases			Advanced Cases			Necropsy	
	Number	Percentage	Exercise test Percentage	Number	Percentage		Number	Percentage
Normal records	19	95	75	19	16		2	6
Pathologic electrocardiographic findings	1	5	25	98	84		33	94
Inverted T ₁ or T ₁ , T ₂ and T ₃	1	5	10	78	66		28	80
Diphasic or flat T ₁ or T ₁ and T ₂	1	5	10	29	24		7	20
ST segment deflection	2	10	25	66	56		20	57
Intraventricular block	0			31	26		10	28
Prominent Q ₁	0			11	9		5	14
Triphasic complex	0			10	8		8	22
Low voltage	1	5	15	12	7		7	20
Slurred notched QRS	3	15	25	28	24		18	51
Left axis deviation	19	95	95	96	82		32	91
No axis deviation	1	5	5	21	18		3	9
Auricular fibrillation	0			8	7		2	5
Arrhythmia	0		25	16	13		7	20

in 2 cases, and 1 case showed a normal electrocardiogram. Two cases had auricular fibrillation, and left bundle branch block occurred four times. In patients without coronary ostial involvement we observed left axis deviation in all cases. Eight cases showed an inverted T₁ or T₂. Q₃ was prominent in 1 case. Six cases revealed a depressed ST segment in two or more leads. Low voltage, auricular fibrillation, or bundle branch block did not occur in this group.

Turning now to the group of 6 cases of coronary ostial stenosis associated with coronary thrombosis, 4 cases showed left axis deviation with inverted T₁ and T₂. A prominent Q₃ occurred four times. Two cases without left axis deviation revealed inverted T₁, T₂, and T₃, with a prominent Q₃. One case showed auricular fibrillation (Table 1).

Case Reports

Case 1—W M, a garage worker, aged 38, had had ten admissions to the hospital since July, 1938. He complained chiefly of dyspnea, substernal pain, and oppression. These symptoms became progressive and more severe. In September, 1938, he entered the Polyclinic Hospital because of these symptoms and developed rapidly increasing dyspnea and paroxysmal nocturnal dyspnea, with attacks of substernal pain, squeezing in character, which became more frequent and more severe.

Physical examination of the heart revealed the point of maximal impulse in the sixth space at the anterior axillary line. A soft systolic and a blowing diastolic murmur was heard over the aortic area and the left sternal border. There was a Corrigan pulse with normal sinus rhythm. Blood pressure was 140/40.

Laboratory Data. Blood Wassermann was 4 plus, spinal Wassermann was negative. An x-ray of the heart revealed a moderate enlargement in all diameters and accentuation of the left ventricular curve, with minimal widening of the ascending aorta, width 7.0 cm. Neither amino-

phylline or nitroglycerin were efficacious in relieving attacks of substernal pain and depression which became more severe and more frequent. These episodes, accompanied by the simultaneous development of severe dyspnea and orthopnea, were the most striking features of his illness. Patient died suddenly on March 4, 1939.

Electrocardiogram taken January 28, 1938, showed normal sinus rhythm with no axis deviation, inverted T₁, diphasic T₂, prominent Q₃ with upright T₃. Electrocardiogram taken January 25, 1939, revealed normal sinus rhythm with inversion of T₁, T₂, and T₃, marked digitalis effect with no deviation of electrical axis. Marked ST segment displacement in leads I and II (Figs 1a and b).

Necropsy revealed syphilitic aortic valvulitis. The heart weighed 700 grams. Partial obstruction of right coronary ostium permitting the entrance of only a small probe. Left coronary rising in normal position with normal patent ostium. Neither coronary showed any obstruction throughout its course.

Case 2—F S, a seaman, aged 39, was first admitted January 3, 1935, with acute congestive failure. Patient had had sixteen admissions to the hospital. His chief complaint was dyspnea with frequent attacks of nonradiating substernal pain.

Physical examination revealed an orthopneic, cyanotic patient with marked distention of neck veins. His heart was markedly enlarged to the left. The point of maximal impulse was in the sixth space at the midaxillary line. There was a double harsh blowing murmur over aortic area and left sternal border. Blood pressure was 144/50, and there was a Corrigan pulse. The patient responded fairly well to mercurial diuresis and digitalis. He received bismuth and potassium iodide at the syphilis clinic. In 1938 he began to have auricular fibrillation, and his course was slowly and progressively downward. Attacks of substernal pain and paroxysmal dyspnea became more frequent. He died on February 10, 1939.

An electrocardiogram taken on January 24, 1935, showed left axis deviation with normal

FIG 1a Serial electrocardiograms on case report. Electrocardiogram on January 28, 1938, showed normal sinus rhythm with no axis deviation, inverted T_1 , diphasic T_2 , prominent Q_3 , with upright T_3 . Ventricular rate 100 per minute.

FIG 1b Electrocardiogram on January 25, 1939, revealed normal sinus rhythm with inversion of T_1 , T_2 , and T_3 , marked digitalis effect with no deviation of electrical axis. Marked ST segment displacement in leads I and II.

sinus rhythm, flat T_1 , notched and slurred QRS in lead III. An electrocardiogram taken on July 8, 1938, revealed left axis deviation with auricular fibrillation, inverted T_1 , flat T_2 , with diphasic T_3 . An electrocardiogram taken on January 3, 1939, showed left axis deviation with auricular fibrillation, inverted T_1 , with notching of the ascending segment of the QRS, flat T_2 , slurred QRS with elevated ST segment and deep inverted T_3 , marked digitalis effect. An electrocardiogram taken on February 4, 1939, showed left axis deviation, auricular fibrillation with auricular flutter, Heilmann's notch in lead I, inverted T_1 , notched and slurred QRS in lead II, inverted T_2 , slightly elevated ST segment with inverted T_3 (Figs 2a, b, c, d).

Necropsy revealed syphilitic aortic valvulitis. The heart weighed 520 grains. The coronary arteries arose within the sinuses of Valsalva and were of normal distribution. Both coronary orifices were completely narrowed, yet were of ample caliber throughout the branches.

Group 2—We have studied and correlated the clinical course together with the electrocardiograms of a group of 117 patients who were admitted to the hospital with signs of congestive failure or intercurrent infection. Subsequently the clinical diagnosis of cardiovascular syphilis was made. None of these cases was autopsied.

Among the 117 cases analyzed, 76 (64.9 per cent) occurred in men and 41 (35.1 per cent) occurred in women. The youngest was 23 and the oldest was 78. The Wassermann test was positive in 91 cases. There were 88 white and 39 Negro patients. High blood pressure complicated 58 cases.

The clinical diagnosis was aortic insufficiency in 86 cases, aneurysm in 18, and aortitis in 25. The aorta was dilated and

FIG 2a

FIG 2b

FIG 2c

FIG 2d

FIG 2a. Serial electrocardiogram on case report. Electrocardiogram on January 24, 1935, showed left axis deviation with normal sinus rhythm. Flat T_1 , notched and slurred QRS in lead III.

FIG 2b. Electrocardiogram on July 8, 1938, revealed left axis deviation with auricular fibrillation, inverted T_1 , flat T_2 , with diphasic T_3 .

FIG 2c. Electrocardiogram on January 3, 1939, showed left axis deviation with auricular fibrillation. Inverted T_1 , with notching of the ascending segment of the QRS, flat T_2 , slurred QRS with elevated ST segment and deep inverted T_3 , marked digitalis effect.

FIG 2d. Electrocardiogram on February 4, 1939, showed left axis deviation, auricular fibrillation with auricular flutter (2:1), Hemann's notch in lead I, inverted T_1 , notched and slurred QRS in lead II. Inverted T_2 . Slightly elevated ST segment with inverted T_3 .

widened in 85 cases, and the heart was enlarged in 93 cases. Most of the patients had a negative history with insufficient or no treatment.

The electrocardiographic changes were pathologic in 84 per cent of the cases observed. It will be noted that left axis deviation occurred in 82 per cent. A rather high incidence of inverted isoelectric or diphasic T wave (lead I 44 cases, leads II and III 8 cases, leads I and II together 22 cases) was seen corresponding with the findings of many observers. ST segment deviation was found in 56 per cent of the cases. Intraventricular block occurred in 26 per cent and low voltage occurred in 12 per cent of these cases.

Group 3—Another study was made of the early stage of cardiovascular involvement in a group of 20 patients, 13 with uncomplicated aortitis and 7 complicated by aortic insufficiency. There were 14 men and 6 women in this group—18 white and 2 Negro patients. Their ages ranged from 27 to 42 years, and their infection dated from a period of four to twelve years earlier. None of these patients had had sufficient specific treatment. All had positive Wassermann tests and normal blood pressures.

Aortalgia and dyspnea on exertion occurred

in 10 cases, 7 were without clinical symptoms. Nine showed a systolic murmur over the aortic area and a sharply accentuated, aortic, second sound. The 7 cases of aortic insufficiency showed a diastolic murmur. The aorta and heart were normal on x-ray examination in the uncomplicated cases and were moderately widened in 2 cases of aortic insufficiency.

The electrocardiogram showed left axis deviation in all uncomplicated cases but no other pathologic changes before and after the exertion test. Besides left axis deviation, the 7 cases of aortic insufficiency showed inverted T_1 in 1 case and negative ST_1 and ST_2 in another case. The remaining 5 cases were normal. After the exertion test, 5 out of these 7 cases showed marked pathologic changes consisting in negative ST_1 and ST_2 , with positive ST_3 , (2 cases), negative ST_2 and ST_3 , (2 cases), and negative ST_3 (1 case), all with numerous extrasystoles from ectopic foci.

Electrocardiographic changes of the kind under discussion are illustrated in the following two case reports.

Case Reports

Case 3—E. P., a white man, aged 27, was admitted to Bellevue Hospital on February 16,

Figs 3a and b Electrocardiographic study with positive exercise test. The first (a) was taken while patient was at rest and shows left axis deviation, normal sinus rhythm, slight depression of ST junction in lead I and elevated ST deflection in lead III. The second (b) was taken immediately after the exercise test and shows a deep inversion of the T wave in lead III as a positive reaction.

1940, and was discharged on March 17, 1940. Diagnosis of meningovascular syphilis, aortitis, and coronary ostial stenosis was made. He entered the hospital because of staggering gait and numbness of feet. He had had a chancre seven years before.

Physical examination revealed that the pupils were equal and reacted to light and accommodation, with no nystagmus. The heart was not enlarged, and no murmurs were heard. The aortic second sound was greater than the pulmonary second sound. There was normal sinus rhythm, with blood pressure 120/62. There was a weakness of the extensors of the left upper extremity and both lower extremities, with definite ataxia. The sense of position was markedly impaired for both legs, with absent ankle and knee jerk. Abdominal reflexes were present.

Laboratory Data: Blood and spinal Wassermann were 4 plus. The colloidal gold curve was 0000011100. The heart and aorta were not enlarged on x-ray examination. The presence of increased spinal fluid pressure with lymphocytic cells and high protein content suggested an active process causing posterior column signs.

Two sets of electrocardiograms are shown (Figs 3a, b). The first (a) was taken while the patient was at rest and shows left axis deviation,

normal sinus rhythm, slight depression of ST junction in lead I, and elevated ST deflection in lead III. The second electrocardiogram (b) was taken immediately after the exercise test and shows a deep inversion of the T wave in lead III as a positive reaction.

Case 4—O F, a bricklayer, aged 33, was admitted February 10, 1940, with a recent episode of intercostal pain due to a tabetic crisis. Although he could not recall having had a chancre and gave no history of gonorrhea, the Wassermann test was 4 plus. The patient had never suffered from substernal pain or paroxysmal dyspnea.

Physical examination revealed a well-developed, well-nourished adult man. His pupils were equal and reacted to light and accommodation. The point of maximal impulse was 9 cm. from the midsternal line at the fifth intercostal space. Soft systolic and diastolic murmur at the base was transmitted lower down to the left side of the sternum. There was an apical systolic murmur, normal sinus rhythm, and a Corrigan pulse. The blood pressure was 120/50.

Laboratory Data: Blood and spinal Wassermanns were 4 plus. The colloidal gold curve was 3455544333. An x-ray of heart revealed no enlargement of left ventricle. There was a slight widening of the supracardiac portion of the aorta.

As in Case 3, two sets of electrocardiograms were taken (Figs 3c, d). The first set (c) was taken while the patient was at rest and shows normal sinus rhythm with no deviation of the electrical axis. The second set (d) was taken after the exercise test and reveals typical left axis deviation with frequent extrasystoles, slight depression of ST junction in lead I, T₂ diphasic, inverted seagull T wave in lead III. At the end of the exercise test the patient complained of sharp substernal pain with great anxiety (as of impending dissolution), which was relieved by nitroglycerin.

Discussion

Difficulties encountered in the early diagnosis of both uncomplicated aortitis and coronary ostial stenosis are very great indeed, especially when the previous history and Wassermann are negative. In early uncomplicated aortitis the electrocardiogram is mostly normal and, in our experience, becomes abnormal only when the process spreads to the valves or involves the coronary arteries. The electrocardiogram in the majority of advanced cases of cardiovascular syphilis shows quite marked pathologic changes that are indicative of disturbed coronary circulation with cardiac enlargement and frequently digitalis effect. Although the electrocardiographic findings are nonspecific, they are of the greatest value both in the diagnosis and prognosis of syphilitic heart disease.

In the electrocardiogram we have a valuable means of arriving at an early objective diagnosis in these cases. Taken in the normal manner, the electrocardiogram is normal in 95 per cent of our early cases. However, an electrocardiographic study made with the graduated exercise test, consisting of rapidly climbing steps, trotting, and other means of physical exertion which impose a burden on the heart, has possibilities as yet unrealized.¹⁴ With this diagnostic procedure one is able to detect transient myocardial anoxemia induced by exertion, frequently with cardiac pain. In our group of early cases only 5 per cent showed a pathologic electrocardiogram before the exercise test, whereas 25 per cent showed an abnormal response to the exercise test.

The electrocardiogram, when used in conjunction with the exercise test, is recorded not only immediately after effort but also at intervals ranging from one to two, five, and ten minutes following exertion. Thirty minutes after completion of the exercise test the electrocardiogram returns to normal. Only positive findings should be utilized, and only definite changes should be interpreted as pathologic.

Unfortunately, effort increases the heart rate and produces minor changes in the form of the electrocardiogram when the heart is normal. When judging the electrocardiograms taken during the exercise test, one must differentiate between such abnormal changes as may be attributed to myocardial anoxemia and such changes as may normally occur after exertion.

After the graduated exercise test, the patient may experience anginal pain or marked anxiety. When the test is positive, the electrocardiogram shows characteristic upward or downward displacement of the RS-T junction and modifications of the RS-T segment in two or more leads, with changes in the initial deflection and ectopic beats. This test is harmless if applied properly and graduated individually according to the daily work of the patient. Occasionally a normal exercise test is observed in aortitis, despite complete occlusion of one coronary ostium due to collateral circulation.

Wood and Wolferth²² studied the electrocardiogram of patients with angina pectoris after physical exercise and found marked changes, although they concluded that this test is without diagnostic value in angina pectoris. On the other hand, both Scherf¹⁵ and Wilson²¹ have noted that the exercise

FIGS 3c and d. The first (c) was taken while the patient was at rest and shows normal sinus rhythm with no deviation of the electrical axis. The second (d) was taken after exercise test, reveals typical left axis deviation with frequent extrasystoles. Slight depression of ST junction in lead I, T₁ diphasic, inverted seagull T wave in lead III as a positive reaction.

test is an important diagnostic procedure in the interpretation of borderline electrocardiograms in coronary sclerosis and syphilitic coronary ostial stenosis. In young subjects, where there is an absence of coronary sclerosis, the exercise test furnishes additional objective evidence as a diagnostic procedure in the detection of the state of the coronary arteries in syphilitic heart disease. A positive test in a syphilitic subject certainly permits one to make the diagnosis of aortitis which has led to a stenosis of the coronary orifices.

In a controlled series of 50 cases under 45 years of age with presumably normal hearts or merely essential hypertension, the electrocardiographic study with the exercise test was performed and one positive result was obtained, while in our group of 20 cases of early cardiovascular syphilis of corresponding

age and sex, five positive exercise tests were observed. Thus, the incidence of a positive exercise test was twelve times more frequent in the syphilitic group than in the nonsyphilitic group.

This differentiation of the syphilitic group presents additional evidence that is of greatest value in this diagnostic procedure, permitting one to make the diagnosis of aortitis with coronary ostial stenosis. A positive test with or without angina pectoris in a syphilitic under 45 years of age is certainly strongly suggestive of aortitis with involvement of coronary orifices. After 50, a positive test with or without the presence of cardiac pain is due rather to coronary sclerosis on an inactive syphilitic basis. Therefore, it is self-evident that an electrocardiographic study made with a positive exercise test in a syphilitic case under 45 years of age enables one to make the diagnosis of latent coronary ostial stenosis.

Although there are no electrocardiographic pathognomonic signs of syphilitic heart disease, the electrocardiogram may be of the greatest value to the diagnosis and prognosis in the later stages of the disease. From the observation of our cases it is evident that the electrocardiographic changes are more marked where the coronary ostia are involved. There are, however, distinct pathologic changes in cases of open coronary ostia. The question arises as to what produces the pathologic electrocardiographic changes and whether these could not be due rather to aortic insufficiency with a coexistent cardiac dilatation than to the state of the coronary ostia.

In seeking an explanation for the appearance of an abnormal electrocardiogram in the patients without coronary ostial stenosis, it may be noted that these patients have a large heart and show the type of ventricular complex which has been attributed to marked hypertrophy and dilatation of the left ventricle. However, some cases of aortic insufficiency with an enlarged heart did not show an abnormal electrocardiogram, so that its association with left ventricular hypertrophy is not obligatory. The state of the myocardium has been demonstrated as an even more important factor than the participation of the aortic valve. It is well known that the broadest QRS complex in the electrocardiogram with the most severe alterations in the ventricular complex, as demonstrated electrocardiographically, may be found in aor-

itic aortitis in the absence of aneurysm or other gross deformities of the aorta cannot be safely established before the advent of aortic insufficiency. The difficulties encountered in making the diagnosis have been presented, and it would be of great importance to differentiate between syphilitic aortitis and coronary ostial stenosis. Since the clinical findings and subjective symptoms do not enable us to establish the diagnosis, the electrocardiogram is of great value, being the most sensitive detector of the state of the coronary arteries. Although one is not justified in making the diagnosis of cardiovascular syphilis on the basis of the electrocardiographic findings alone, the presence of a pathologic electrocardiogram with a positive exercise test is at present the only safe method of establishing the diagnosis of aortitis with coronary ostial stenosis at an early stage.

Summary

1 Difficulties in diagnosing cardiovascular syphilis are briefly outlined, and the importance of the involvement of the coronary ostia in prognosis is stressed.

2 Analysis is made of 172 cases. Included are 20 early and 117 advanced cases, 35 with necropsy. These comprise 39 cases of uncomplicated aortitis, 23 cases of aneurysm, and 124 cases of aortic insufficiency.

3 An abnormal electrocardiogram with progressive serial changes is found to be (in the absence of acute myocardial infarction) strongly suggestive of syphilitic aortitis with probable coronary ostial stenosis.

4 It is demonstrated that a normal or borderline electrocardiogram in a syphilitic case under 45 years of age may become positive after the exercise test is given, thus establishing the diagnosis of aortitis with probable coronary ostial stenosis.

5 The importance of the electrocardiographic study made with the exercise test is emphasized as the only safe means of establishing the diagnosis of latent coronary ostial stenosis.

6 Routine use of the electrocardiographic study and exercise test in early cases with a systematic follow-up in subsequent years is urged in order to discover cardiovascular syphilis at an earlier stage than has been possible heretofore.

WANTED A MEDICAL AXMAN

Under the humorous heading of "Fuel for Heating Hospital Smoking Rooms," Dr Floyd Burrows contributes some intriguing reflections to the *Bulletin of the Onondaga County Medical Society*. In a section entitled "Dead Timber," he writes

"No doubt exists in many minds that there is standing in the medical preserve at present too much dead timber. Our professional forest needs some pruning and considerable reforestation. Unquestionably there are men in our ranks who have lagged far behind the parade in marching with medical science. Their brains do not contain much more medical knowledge than they possessed when they were handed a sheepskin. An eminent physician once remarked that one must learn medicine all over every ten years. I believe that statement contained as much truth as could be squeezed safely by a pair of tongs in one sentence.

"If the standards of medical practice are to be maintained at a level consistent with modern expectations, an examination ought to be made of each practitioner every decade. I do not infer that he should take a quiz in chemistry, anatomy or physiology. But, he should be given an examination in clinical medicine and

surgery sufficient to determine whether he has kept pace with the developments of diagnosis, treatment and general management of diseased conditions of all kinds within the field of his practice. He should be on his toes in regard to early diagnosis of all maladies—especially those which need specific treatment.

"By whom such examinations should be conducted might be open to considerable debate. But it would seem that this matter could be worked out satisfactorily if it were turned over to medical men of unquestioned honesty and wide experience who have become eminent. Such men have fought over the battlefields of illness and have diversified knowledge of all maneuvers used in fighting disease. A group of such men should be able to decide the worthiness of all candidates. If a man could not pass a test he should be put on probation for one year and then given another test. In case he failed the second time he should be eliminated automatically from medical practice. If such a plan or something analogous were in vogue doctors would be obliged to study and keep up to date. Those who did would have nothing to fear, while those who did not could be eliminated and not be a serious detriment to the others."

"HOW DOTH THE LITTLE BUSY B₁"

The results of recent investigations of vitamin B₁ deficiency "suggest that efficiency for prosecution of a war can be increased by the simple expedient of providing a very little more of vitamin B₁ than the public is receiving. This subject is also receiving consideration by those responsible for our national defense," the *Journal of the American Medical Association* declares in an editorial.

"England, locked in the struggle of total war and conscious of the importance of maintaining at high levels the strength and courage of its people, has fortified margarine with vitamin A and restored calcium and thiamin hydrochloride (vitamin B₁) to flour," the editorial states. "This action was taken on advice from the Medical Research Council and with the recommendation of leaders in nutritional research. Sir John Orr and Dr J. C. Drummond were largely responsible. In consequence, ill effects from deficiency of calcium and vitamin B₁ will be minimized in England notwithstanding lower rations. Vitamin A will accompany whatever edible fats remain available, and calcium and vitamin B₁ will be supplied as long as any cereal food is left."

POSTGRADUATE MEDICAL EDUCATION

A Sanitation Symposium was arranged for the Oswego County Medical Society at the Elks Club, Oswego, New York, on January 29, 1941, at 6 30 P. M. The program was as follows: "Milk Supplies," by Mr. W. D. Tiedeman, C. E., chief, Bureau of Milk Sanitation, Division of Sanitation, State Health Department, Albany, New York, and "Water Supplies," by Mr. C. R. Cox, C. E., chief, Bureau of Water Supplies, Division of Sanitation, State Health Department, Albany, New York. Special reference was made to emergency procedures in cases of catastrophe. This symposium was arranged and presented in cooperation with the Division of Sanitation of the State Department of Health, Albany, New York.

WHY CHANGE?

Investigation of European medical systems on the spot by the secretary of the Wisconsin State Medical Society uncovered the significant fact that the Irish and Germans in Milwaukee are far healthier than the Irish in Ireland or the Germans in Germany.

PUBLIC HEALTH ASPECTS OF CARDIOVASCULAR SYPHILIS IN NEW YORK CITY

JOSEPH WEINSTEIN, M D , M S P H , New York City

SYPHILIS has been recognized as one of the most pressing public health problems today in the United States and has received considerable attention both from clinicians and public health administrators throughout the country. Cardiovascular syphilis, including simple aortitis, aortic valvular insufficiency, and aneurysm, is a matter of great concern to the community because, although it is a late manifestation of this communicable disease, it affects a relatively substantial proportion of the population, often with severe disabling results, and because it is largely preventable.

In order that the importance and significance of preventing aortic syphilis may be better comprehended, it is desirable that the size of the problem be realized. This requires a consideration of morbidity and mortality statistics and an estimate of the economic waste occasioned by this disease.

Probable Prevalence and Distribution

It must be pointed out at the outset that morbidity and mortality reports for syphilis do not present a true picture of the prevalence of this disease and its late manifestations because of incomplete reporting. However, it is believed that the following information may serve to illustrate the importance of syphilitic heart disease as a community problem.

Cohn¹ and Emerson,² on the basis of several sickness surveys conducted by eminent authorities, have each conservatively estimated that roughly 2 per cent of the total population on any given date will be found to have some form of recognizable heart disease. In a study of 1,001 cases of organic heart disease among clinic and private patients in New York City, Wyckoff and Lunn³ found 8.6 per cent of the cases to be syphilitic in origin. Of these, 88 per cent occurred in men and 12 per cent in women, 16.3 per cent in persons under the age of 40 and 83.7 per cent above that age, with the highest peak (71.3 per cent) in age group 40-59. Applying the above ratios to the population of New York City in 1938 (7,491,790), we may reasonably assume that the number of patients with aortic syphilis

in this community probably amounted to roughly 13,000 during that year.

The available mortality statistics for organic heart disease are based on deaths recorded in accordance with the *International List of Causes of Death*, which is not so classified as to make it possible to distinguish between the different etiologic types of heart disease. Lacking such information, we may, however, utilize the recorded deaths from aneurysm which permit a consideration of the mortality trend of cardiovascular syphilis. From a medical point of view, the story of cardiovascular syphilis in the main centers about the damage the disease produces in the aorta, and aneurysm in the vast majority of instances is the result of syphilitic infection of the aorta. Referring to Table 1 and Fig. 1, it is interesting to note that the number of deaths from aneurysm per 100,000 total population in New York City, with some periodic fluctuations, has varied but slightly during the past fifteen years.

From 1.9 in 1924, the rates had gradually increased year by year to 2.5 in 1928, then gently decreased to 1.5 in 1931, and maintained this level until 1934. They have risen, during the past four years, with slight variations from 1.5 in 1934 to 2.2 in 1938. A study of the age-specific death rates (Table 2 and Fig. 2) likewise shows that no marked change has taken place in the mortality from this type of heart affection. Thus, it is quite apparent that in the past syphilis in a large proportion of the population has not been recog-

TABLE 1—DEATH RATES FROM SYPHILIS PER 100,000 ESTIMATED POPULATION, NEW YORK CITY, 1924-1938, INCLUSIVE*

Year	Syphilis	Locomotor Ataxia	General Paresis	Aneurysm	Total
1924	7.8	1.3	4.5	1.9	15.5
1925	7.2	1.0	5.2	1.8	15.2
1926	7.1	1.2	4.5	2.1	14.9
1927	8.3	1.0	3.4	2.3	15.0
1928	7.7	1.0	3.2	2.5	14.4
1929	7.9	1.2	2.9	2.8	14.8
1930	8.8	0.9	3.1	2.0	14.8
1931	7.9	0.7	2.5	1.6	12.6
1932	8.5	0.5	2.1	1.0	12.7

*Compiled from figures, *Annual Reports*, New York City Department of Health, 1924-1938

FIG 1

nized early enough or sufficiently treated to avoid involvement of the cardiovascular system. The death rates increase with age, the lowest rates are noted in the age group under 40 years, the highest in the group 60 years and over.

It is interesting to compare the mortalities from aneurysm with those of locomotor ataxia and general paralysis of the insane (Table 1 and Fig 1). While no conspicuous changes from a public health point of view have been noted in either aneurysm or locomotor ataxia during the past decade and a half, conditions differed somewhat in the case of general paresis. Here the death rate dropped from 52 per 100,000 population in 1925 to 19 in 1933 and fluctuated about this level for the next six years. The sudden and continuous drop of the curve between 1925 and 1933 may probably be accounted for, among other factors, by the introduction of hyperpyrexia and tryparsamide in the treatment of this condition.

Economic Aspects

Aside from the humanitarian appeal, aortic syphilis is a social and economic problem of vast importance. It causes considerable suffering and disability, interferes with the working lives of the affected persons, and, because of the physical handicap and frequent need for hospitalization, it places a tremendous economic burden upon society. Emerson⁶ has

FIG 2

conservatively estimated that for cardiac patients, the population of New York bears a cost of 75 cents per capita per annum. When we apply this ratio to the population of New York City in 1938, the amount of money spent to care for cardiac patients probably amounted to more than five and one-half million dollars during that year. If 8.6 per cent of the cardiac patients in New York City, as found by Wyckoff and Lunge, are syphilitic in origin, approximately one-half million dollars were probably spent on cardiac invalids as a result of syphilis.

The Future Outlook

The most effective way to prevent cardiovascular syphilis is, of course, to avoid syphilitic infection. In persons who have already been infected, the best time for the prevention of damage to the cardiovascular system is during the early stage of the chancre before the spirochetes begin their widespread dissemination.

A substantial reduction in the number of cases and deaths from syphilitic heart disease

TABLE 2—AGE SPECIFIC DEATH RATES FROM ANEURYSM NEW YORK CITY 1924-1938*

Years	Under 40 Years		40-59 Years		60 Years and Over	
	Deaths during three years	Rate	Deaths during three years	Rate	Deaths during three years	Rate
1924-1926	71	0.5	183	4.4	112	9.1
1927-1929	77	0.4	246	5.0	154	10.7
1930-1932	69	0.4	186	4.0	114	8.3
1933-1935	57	0.4	173	3.6	123	8.7

*Compiled from figures Annual Reports New York City Department of Health, 1924-1938

in the future may be anticipated as a result of better diagnosis and more adequate treatment of early syphilis at present. It is well established clinically that syphilis of the aorta appears on the average from fifteen to twenty years after the primary syphilitic infection. In rare instances, there is a more rapid progression. Cases of simple aortitis and aortic insufficiency can be detected earlier than aneurysm. Thus, in general, one would hesitate to predict a significant reduction in the morbidity and mortality from cardiovascular syphilis in less than an average of seventeen years beginning with the present anti-syphilis campaign.

Summary

1. An analysis of the available morbidity and mortality statistics and a consideration of the economic aspects of cardiovascular syphilis in New York City show that this disease is an important public health problem.

2. From a practical public health point of view no conspicuous change has taken place in New York City in the reported deaths from aortic aneurysm during the past decade and

a half. Apparently, syphilis in a number of persons has not been recognized early enough or properly treated in the past to avoid later complications in the circulatory system.

3. The outlook for cardiovascular syphilis in the future is full of promise provided the present efforts in the discovery and treatment of syphilis in its earliest possible stage are continued intensively for an adequate period of time.

4. Past experience has taught us that aortic syphilis will develop in a certain number of individuals despite energetic and prolonged treatment of early syphilis. In this respect more knowledge is wanted, and further efforts in the direction of research on syphilis treatment and its evaluation are indicated.

"A WEDGE FOR WHAT?"

The agreement entered into between Manhattan General Hospital and Local 802 of the American Federation of Musicians may have grave consequences for both the working people of this city and the medical profession, believes the *New York Medical Week*. It is contrary to most of the accepted principles for first-rate medical care and, if extended, will lead to destruction of prevailing standards of service by cut-throat competition among private hospitals for this type of business.

As envisaged at present, the plan contemplates complete hospitalization, including medical care, for unemployed and indigent members of the local and their families. This is a highly praiseworthy objective—but the union makes no secret of the fact that if its plan works successfully for the unemployed it hopes to extend coverage to include all of its 22,000 members and their families.

As described in the *New York Times*, "the new plan calls for the division of the city into eight districts, in each of which the union has retained a physician who is also a member of the staff of the hospital. These physicians will pass upon the needs of unemployed members of the local and their families residing in their districts." There is, of course, no free choice of physician. The practitioners associated with the plan are employees of the union and wholly subject to lay direction.

It will be remembered that last winter the

New York State Legislature held with the medical profession that hospitalization insurance and group provision for medical care should be kept separate because of the different administrative problems involved. The plan under discussion lumps both services together under lay control.

If this scheme is extended to the working, self-supporting members of the union, there will be a mad scramble among other private hospitals to cut in on this business. The usual competitive weapon in such circumstances is the cut price, and we may expect to see scores of schemes for cheap contract practice springing up in other unions, industrial plants, and benevolent organizations. The result will be as demoralizing to the prevailing standards of medical care as the low-grade contract practice which paved the way for compulsory sickness insurance in England.

The only way for the profession to fight this evil is to press its own plans for low-cost, high quality service for the lower income groups, declares the *Medical Week*. People are not impressed by adverse criticism, however justified, unless something better is offered them.

The spread of cut-rate contract medicine would gradually poison the system of independent medical practice. Prompt application of the principles of voluntary nonprofit medical expense indemnity insurance is the sole antidote. It should not be delayed.

Medical Officer "Is your condition organic?"
Disabled Veteran "Doc, I can't even carry a tune."—*Medical Record*

Sickness among industrial workers is showing a downward trend, more among men than women

THE BLOOD WASSERMANN REACTION IN 800 PRIVATE PATIENTS

CONNIE M. GUION, M D , ELISABETH C. ADAMS, M D , and A. PARKS MCCOMBS, M D ,
New York City

IN REVIEWING the literature of the incidence of syphilis, we found that most studies have concerned groups of clinic patients or of the general population. We are reporting, therefore, our results on 800 cases studied in our private practice in New York City. Most of these patients are American-born, well-educated adults, thus, this group differs in its personnel from most of those on whom studies have been made regarding the occurrence of the positive Wassermann test.

Review of the Literature on the Incidence of Syphilis

Jones¹ in 1904 stated his estimate, based on impressions gained over a period of six years, that 75 per cent of patients, mostly Negroes, attending a large general clinic in Memphis, Tennessee, were suffering from syphilis. The incidence of syphilis has been variously estimated and sought by statistical, clinical, laboratory, and autopsy studies in the thirty-five years since then without mention of any correspondingly high figure.

Symmers² in 1916 wrote of positive Wassermann reactions in "over 25 per cent of the enormous number of serums examined" at Bellevue Hospital in New York City. He found evidences of syphilis there in 6.5 per cent of 4,880 necropsies done in the preceding ten years.

Williams³ in 1920 reported the finding of a positive Wassermann reaction in 2.48 per cent of 1,806 pregnant white women and in 16.29 per cent of 2,194 pregnant Negro women admitted to The Johns Hopkins Hospital between 1916 and 1919.

Stokes and Brehmer⁴ in 1920, in a study of 1,143 patients at the Mayo Clinic, found the Wassermann reaction positive in 11.7 per cent of 128 railroad employees, 6.1 per cent of 243 laborers, 3.8 per cent of 236 merchants and tradesmen, and 1.5 per cent of 536 farmers.

Hemsath⁵ in 1931 reported that 4 per cent of 6,800 admissions to the New York Lying-In Hospital in twenty-one months of 1929 and 1930 showed 2 to 4 plus reactions, 884 of

From the Cornell University Medical College and the New York Hospital.

these patients were Negroes, of whom the positive reactors comprised 12 per cent.

Granger⁶ in 1932 found an incidence of 14.75 per cent of strongly positive Wassermann reactions among 2,000 private Negro patients in Brooklyn, 16 per cent showed weak or doubtful Wassermann reactions.

Warthum⁷ reported in 1931 a diagnosis of latent syphilis, based on microscopic criteria, in 43.7 per cent of 386 autopsies done in the decade 1910 to 1920 and in 25.7 per cent of 1,289 autopsies done in the decade 1920 to 1930, or 29.5 per cent in 1,675 autopsies. This material was from the University Hospital at Ann Arbor and represented the average middle- and lower-class population of Michigan.

Rice and Goldberg⁸ in 1936, from census studies done under the auspices of the United States Public Health Service and various agencies involving areas totaling over 27,000,000 population, allowed a conservative estimate that 5 per cent of the population of the United States had syphilis at any one time.

Holloway, Grant, and Bent⁹ in 1937 reported an incidence of 27.4 per cent who showed a positive Wassermann reaction among 12,892 patients from clinics and hospital wards in Memphis, Tennessee. They found 5.9 per cent positive in 836 healthy Negro college students examined.

Pickell¹⁰ in 1938 found a 1 to 4 plus positive reaction in 11.7 per cent of 304 white patients and 48.9 per cent of 233 Negro patients examined in his office in a small Alabama city where patients from rural sections were also included.

Usilton, Hunter, and Vonderlehr¹¹ in 1938 reported data secured from all the clinics and most of the private physicians of Chicago and collected under the direction of the United States Public Health Service and the Works Progress Administration, they showed that 0.44 per cent of the population of Chicago is constantly under medical care for syphilis.

Gastineau¹² in 1938 estimated an incidence of 2.4 to 3 per cent of syphilis among admissions to various hospitals and clinics in rural Indiana.

Brunet and Salberg¹³ in 1939 report, from the Women's Division of the Public Health

Institute in Chicago, an incidence of syphilis of 2 per cent among a group of 913 premarital examinations. They cite the July, 1938, report of the Illinois Health Department of an incidence of 1.9 per cent positive Wassermanns among 47,781 premarital tests.

In the fourth quarter of 1938 the New York City Department of Health¹⁴ examined 144,723 blood specimens for syphilis, 12.2 per cent were found positive. Of 15,524 new patients admitted to the diagnostic clinics during the same period, 13.8 per cent were diagnosed as suffering from syphilis. During the six months ending December 31, 1938, the Department of Health^{14b} also reported that premarital blood tests were done on 58,903 individuals, 0.95 per cent were positive. Of the 52,585 tested at the Bureau of Laboratories of the Department of Health, 1.03 per cent were positive, while only 0.27 per cent of 6,412 tested at private laboratories were positive. It is speculated that persons knowing themselves to be infected would not apply for a license requiring a blood test. It is estimated in the same report that the incidence of syphilis in New York City is not over 1 per cent of the total population.

At the New York Hospital¹⁵ between February 1, 1936, and February 28, 1939, 27,301 patients admitted to the outpatient department were subjected to a Kline test. These were men and women for the most part residents of New York City who applied to the clinic for treatment of some medical problem. The Kline test is done routinely on all medical patients before they are examined by the physician. This group represents, therefore, an unselected cross section of the clinic public. Of these, 1,270 or 4.7 per cent gave a 3 or 4 plus reaction. During the past four years, 122 or 3.7 per cent of 3,303 Kline tests done on private or semiprivate patients at the New York Hospital have given a 4 plus reaction, all of these tests were done at the request of the private physician, some specimens were probably submitted because the disease was suspected, and in many instances more than one specimen was sent for each patient.

It is of interest to note that in 1,000 patients with elevated blood pressure seen in the New York City practice of Dr. Frank S. Mearns¹⁶ between 1916 and 1926 the blood Wassermann reaction was 3 or 4 plus in 3.4 per cent. Most of these patients were seen in consultation and were diagnostic problems, some of them were known to be suffering from syphilis.

These are but a few representative studies

from a great many reports concerning the incidence of syphilis.

Our Data

In our private office between January, 1936, and March, 1939, blood specimens have been taken routinely from each new patient and have been sent to reliable laboratories for a Wassermann test. The series includes 56 men and 744 women, a total of 800 white adults. Of these there were but 3 on whom a Wassermann test was indicated, 2 of the 3 were known to have syphilis, 1 with a positive and the other with a negative Wassermann for a number of years, the other patient, a woman, gave a history of syphilis and showed signs suggestive of the disease. Several patients offering no complaints came to the office for a general "health" examination.

Of the 800 specimens submitted, 775 or 96.87 per cent showed negative Wassermann reactions. Because a negative reaction was reported for the patient who gave a history of contact and showed suspected signs, a specimen of her blood was sent for a Kline diagnostic test, this was reported 2 plus. We, therefore, excluded her from our totally negative group, leaving 774 patients or 96.75 per cent of the 800 with no suspicion of syphilis as determined by the laboratory tests. (It is to be hoped that the negative history in all of these was reliable and that the absence of physical signs of the disease with their negative Wassermanns is proof enough that they are not suffering from syphilis.)

Twenty-five specimens showed a positive Wassermann reaction ranging from plus minus to 4 plus. Of the 800 patients, 3.25 per cent were, therefore, suspected of having syphilis. Of the 25, 2 patients in whom the disease was not suspected admitted, when told the results of the tests, that they had had syphilis. Two others of the group were servants who had been sent by their employer, otherwise, had they sought medical attention, they would have been seen in a clinic. Five of the 25 were men each of these showed a 4 plus reaction. Table 1 gives the details of the series.

Summary

In 800 patients seen in private practice in New York City from 1936 to 1939, a negative blood Wassermann was found in 96.9 per cent or in 775 patients, 1 of whom, however, showed a 2 plus Kline diagnostic test, leaving 96.75 per cent beyond reasonable suspicion of having syphilis from a laboratory point of view. Therefore, 26 patients, or

TABLE 1

Wassermann	First Specimen	Second Specimen*
Negative	774	
Negative but Kline 2+	1	Confirmed
+	10	2 negative 8 not repeated here
1+	3	2 negative 1 not repeated here
2+	1	Confirmed
3+	1	Not repeated here
4+	10	7 confirmed 3 not repeated here

*From patients whose first specimen was not negative

3 25 per cent of the 800 studied, were suspected of having syphilis. Of these 26 patients, only 11 or 1 37 per cent of the 800 cases showed 3 and 4 plus reactions

Conclusion

The incidence of syphilis recorded in the literature varies widely, depending upon the social habits and race of the groups studied, on the accuracy of the study, and on the decade in medicine. Reports range from an estimate of an incidence of 75 per cent among a southern Negro clinic group thirty-five to forty years ago to the finding of 0.95 per cent positive Wassermann reactions among 58,903 premarital tests done in 1938 by the New York City Department of Health. The New York Hospital private and semiprivate patient group is the most nearly parallel to ours. The incidence of 1 37 per cent strongly positive Wassermann tests found in our practice would be expected to be lower than their figures, where an incidence of 3 7 per cent

was found on specimens from sick patients many of whom were tested more than once. Furthermore, our group of patients is composed chiefly of women, in whom the incidence of syphilis is granted to be lower than in men. The New York Hospital group incidence of 3 7 per cent is practically the same as the incidence of 3 4 per cent positive Wassermann reactions noted in 1926 by Dr. Frank S. Meara on a similar series of consultation patients.

The performance of a serologic test for syphilis on all patients is urged.

SECTIONAL MEETINGS OF THE AMERICAN COLLEGE OF SURGEONS

Dates	City	Headquarters Hotel	Participating States
March 10 11 12	Minneapolis	Nicollet	Minnesota, North and South Dakota, Iowa, Nebraska, Montana, Kansas, Wisconsin—Manitoba
March 17 18 19	Pittsburgh	William Penn	Pennsylvania, Ohio, Virginia, West Virginia, Delaware, Maryland, New Jersey, New York, District of Columbia
March 26 27 28	Salt Lake City	Utah	Oregon, Washington, California, Nevada, Idaho, Wyoming, New Mexico, Arizona, Colorado, Montana, Utah

Hospital conferences will be held in connection with each of these meetings. Fellows of the College, members of the medical profession at large, and persons interested in the institutional

care of the sick and injured are invited to the Sectional Meetings, on the final evening of each session, a meeting on Health Conservation, to which the public is invited, will be held.

BROOKLYN UROLOGICAL SOCIETY

At the annual meeting of the Brooklyn Urological Society, the following officers were elected: president, Dr. Emanuel Salwen, vice-president, Dr. James W. McManus, secretary-treasurer, Dr. Samuel E. Last.

TO CUT OR NOT TO CUT?

'Tis better to use the knife too soon
And find our diagnosis wrong
Than to hear that old familiar tune
He's gone to join the heavenly throng."

—Bennett, quoted in *Pennsylvania M. J.*

SYPHILIS IN THE PREGNANT WOMAN

MORTIMER D. SPEISER, M.D., F.A.C.S., New York City

IN ORDER to handle competently the syphilitic prenatal patient, as well as to undertake the study of several problems intimately connected with this phase of syphilis, a special prenatal syphilis clinic was organized at Bellevue Hospital six years ago. While an outgrowth of the prenatal clinic this special clinic operates with the closest cooperation of the regular syphilis clinic. In the last 16,437 deliveries at Bellevue Hospital there were 790 cases diagnosed as syphilis, an incidence of 4.8 per cent. The early recognition of syphilis in the pregnant woman is essential if efficient therapy is to be instituted and if the transmission of this disease from mother to offspring is to be prevented.

Diagnosis

The diagnosis is established on the basis of a complete history, a carefully executed physical examination, and properly controlled serologic tests. An evaluation is made herein of the data elicited with these procedures. A total of 632 cases were studied from this standpoint—580 were classified as acquired and 52 as definitely or possibly congenital syphilis.

Previous therapy was admitted in 57.2 per cent of the acquired cases. In many instances, however, these data were forthcoming only after the patient was confronted with the positive result of a serologic test. An increasing number of patients during the last few years have given such a history—not only because many of our patients have subsequently returned, but also because of the intimate relationship of this special clinic with the regular syphilis clinic many patients have been referred while under treatment as soon as pregnancy had occurred. Besides, throughout the hospital, clinicians have become more syphilis minded, and the diagnosis has been established even in patients being treated for other conditions. An increase has also been noted and a further increase anticipated as the result of present legislative measures requiring routine premarital serologic tests.

In only 9 per cent of the patients was a history obtained of known syphilitic offspring.

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, May 8, 1940.

From the Department of Obstetrics and Gynecology, Third Surgical Division, Bellevue Hospital.

who either died as the result of their infection or were under treatment. This did not include those children who were examined subsequent to the establishment of a diagnosis in the mother. Of course, the history of syphilis in previous offspring does not absolutely prove the presence of syphilis in the mother, for on rare occasions the infant may have acquired syphilis during its postnatal existence.

In the acquired group a history of lesions that might be interpreted as early syphilitic manifestations could be obtained in 21.2 per cent of the cases. Thus, approximately 1 out of 4 pregnant females with acquired syphilis gave such a suggestive history of early manifestations. It must be noted here that in many instances patients willfully or otherwise withheld such information regarding their syphilitic infection until confronted with the positive result of a serologic test. In 1.4 per cent there was a history of late manifestations.

Previous late abortions, premature deliveries, macerated or otherwise, as well as term stillbirths, particularly when repeated and which could not readily be explained, were interpreted as possibly syphilitic in origin and occurred in 18.8 per cent of the cases. In 24.7 per cent no significant data could be elicited in the history regarding a previous syphilitic infection.

In the congenital group a history of treatment was obtained in 65 per cent of the cases, while 88 per cent gave a history of previous lesions highly suggestive of this disease.

A properly executed physical examination at the time of admission to the prenatal syphilis clinic revealed early syphilitic lesions in 8.1 per cent of the patients, late lesions in 3.3 per cent—a total of 11.4 per cent. While spinal fluid examinations and roentgenograms of the heart and aorta were done as a routine postpartum, this information was not employed as a diagnostic factor in this study. Obviously then, 88.6 per cent of the patients with acquired syphilis were clinically latent and, therefore, revealed no physical findings on which to base a diagnosis. In the congenital group, manifestations were present in 65 per cent.

Value of Serologic Tests

The final step in the diagnosis is the em-

ployment of a serologic test or tests. At Bellevue Hospital only the complement fixation test is employed using both alcoholic and cholesterinized antigens. In 24.7 per cent of the cases the diagnosis was established on the basis of only repeated strongly positive Wassermann reactions. In 37.6 per cent there was a strongly positive Wassermann reaction as well as a highly significant or suggestive history. Many times, the positive reaction offered the first clue to the presence of syphilis, and additional data were elicited upon further scrutiny at this time. In 16.5 per cent there was a positive Wassermann reaction with associated physical findings, while in 21.2 per cent there was a negative or equivocal reaction with a history of previous treatment.

From this, one can readily see how valuable a serologic test can be in establishing the diagnosis of syphilis in the pregnant woman. The Wassermann test is done as a routine on all prenatal patients, and it is repeated in all those instances where the results are other than negative. Where equivocal results have been obtained (such as plus minus, 1 or 2 plus), a repeat Wassermann and, if possible, a flocculation test may yield a more decisive reaction. In those instances where the results of neither test are sufficiently informative, the case must be restudied from the standpoint of history and physical findings. In addition, previous offspring, husband, and mother should be subjected to examination, and the performance of serologic tests should be made upon them. Only in this fashion may one come to a definite diagnosis in these cases.

The ideal serologic diagnostic test for syphilis should possess complete sensitivity and absolute specificity, but unfortunately such a perfect test does not exist. The study by the United States Public Health Service on the evaluation of serologic tests for syphilis indicated comparable values for efficient complement fixation tests and efficient flocculation tests.¹ However, the fact that discrepancies may occur in either direction with both complement fixation and flocculation tests offers the soundest reason for the employment of both as a routine procedure. When the results are positive, they act as mutually supplementary aids. Many modifications of the Wassermann test, however, seem to show variations in sensitivity. This situation is unavoidable unless some central control can assure uniform results throughout the country. This is being attempted by the

Committee on Evaluation of Serodiagnostics Tests for Syphilis. The New York State Department of Health Laboratories also make an effort to clarify this difficulty by reporting accurate quantitative results of their complement fixation test. With such a careful control the results of complement fixation and flocculation tests compare very closely.

It has been stated that false positive reactions have been obtained due to pregnancy. In a study by the United States Public Health Service where the standard Kahn, the diagnostic Kline, or the Kolmer modification of the complement fixation tests were employed on 54 nonsyphilitic pregnant women, not a single serum yielded either a doubtful or a positive result.¹ It is also my impression that pseudopositive reactions with these tests do not occur with any greater frequency in the pregnant woman than in the nonpregnant one. However, it must be admitted that on extremely rare occasions a false positive result may be obtained. How is one to detect it? Where only a single test is done, a positive reaction always requires repetition to rule out either a clerical error or an error in the performance of the test that results in a technical false positive reaction. It has been reasonably established that tuberculosis, diabetes, anesthesia, malignancy, jaundice, fever, and hypercholesteremia are not capable of producing a false positive reaction with any degree of frequency. Biologic false positive results may occur, however—namely, those caused by the presence in the serums of actual reagin in the absence of syphilis, these reagins being capable of producing both a positive Wassermann and a positive flocculation test. This reaction is most frequently encountered in yaws and to a lesser degree in leprosy and malaria. A few other conditions, such as relapsing fever, infectious mononucleosis, etc., supposedly are capable of sometimes producing a false positive reaction, but this requires further verification. From what has been said then, the possibility of a truly false reaction is extremely rare when it occurs with the employment of repeated tests or two different tests on serums from the prenatal patient who presents no other significant history or physical findings. In these rare instances Kahn's new "verification test" with its differential temperature procedure may offer a very valuable method of differentiating the false positive from the truly positive reaction.² On the basis of this infrequency of false positive reactions, it is justifiable to treat every pa-

tient who is pregnant and whose serum persistently yields a strongly positive reaction with standard tests, otherwise one may be guilty of not having prevented the possible transmission of the disease to the offspring.

The Kahn presumptive test and the Kline exclusion test are hypersensitive and may detect the presence of reagin in a nonsyphilitic individual. A persistently positive Wassermann test and a negative flocculation test may infrequently be encountered where the negative flocculation test may be due to the so-called prozone phenomenon. By dilution this result may become distinctly positive.

Negative reactions occurring in syphilitic individuals are encountered and have been ascribed to pregnancy. With efficient serologic tests this should be an infrequent occurrence and may not be blamed entirely on the pregnancy, for a similar condition may exist in late and latent syphilis uncomplicated by pregnancy. One occasionally finds a patient who delivers a frankly syphilitic child yet whose maternal Wassermann, which was done early in pregnancy, was found to be negative. This reaction is not necessarily a false negative one because the patient may have acquired syphilis sometime after the performance of this first test. These cases could only be detected by doing a serologic test not only early in pregnancy but during the last trimester as well.

The Effect of Pregnancy upon Syphilis

Some authorities contend that pregnancy supposedly exerts a beneficial effect upon the course of a syphilitic infection. This is apparently the diametrically opposite effect that pregnancy has or may have upon most other chronic diseases. Regarding the early manifestations, when pregnancy and infection coincide, Moore feels that the lesions are either entirely absent or much milder in character than those encountered in the absence of pregnancy.^{3,4} It must be noted that an absence of a primary lesion in the nonpregnant female is not unusual and, furthermore, that when present it may be overlooked because it occurs, when the infection is genital in origin, on the cervix in 44 per cent of the cases.⁵ The inability of self-inspection and the absence of subjective symptoms are factors which prevent its recognition. In addition, since most cervical chancres are erosive, their innocuous character hinders detection except by those physicians who are constantly on the alert. Actually then, pregnancy may not be such an

important factor in the inhibition of early lesions. It is my impression that when secondary lesions are encountered about the genitalia in a pregnant woman these lesions are apt to undergo luxuriant growth due to congestion and turgescence of the parts involved. Many observers feel that pregnancy is capable of preventing the later manifestations of syphilis, particularly involvement of the central nervous system. It is premature at this time to make any contradictory statement, but it would seem that the inhibition of central nervous system involvement while present was not sufficiently marked to feel that pregnancy was the entire factor.

The Effect of Syphilis upon Pregnancy

While the effect of pregnancy upon syphilis offers a fertile field for continued observation and subsequent deductions, there is little doubt as to the disastrous effect of syphilis upon pregnancy. There were 95 untreated mothers with syphilis who delivered 97 babies (2 twins), and premature terminations occurred in 51.5 per cent of the cases. In 81.5 per cent there was a disastrous result—deaths due to syphilis or live born babies with syphilis—while only 13.4 per cent were salvaged free from the disease.

Faulty presentations arising in this group occurred in 12.4 per cent because of the high incidence of prematurity and stillborn fetuses. The length of labor in the women suffering from syphilis showed no deviation from the normal, and, conceivably, the only patient who might be expected to have a prolonged labor as the result of her syphilis per se would be the rare instance in which an ulcerative chancre of the cervix was sufficiently phagedenic in character to have caused enough destruction with ultimate replacement fibrosis to account for a cervix that was not conducive to normal dilatation. In patients with early lesions who had received no treatment, 54 per cent had a morbid postpartum course. In the entire untreated group, irrespective of the presence of lesions, the morbidity was 23.1 per cent.

Hemorrhage, placenta praevia, and premature separation were not encountered with any greater frequency in the syphilitic group than in the nonsyphilitic group.

Treatment

The diagnosis is but half the problem, since the transmission of the disease from mother to offspring with its consequent disastrous results can only be prevented by adequate

treatment While no hard and fast rules can be set down, certain guiding principles can be formulated, bearing in mind that the arsenicals are by far the drugs of choice and that transmission of the disease takes place sometime after the sixteenth week of gestation. Any plan of treatment must depend upon the following factors

(1) The presence or absence of medical or obstetric contraindications to therapy These may be either of short or long duration The presence of a severe nephritis may prevent the employment of any therapy, while an acute infectious process such as pneumonia may call for only a temporary cessation of treatment Treatment is discontinued in the face of obstetric complications such as pernicious nausea and vomiting and severe progressive toxemia Fortunately, all of these conditions are infrequently encountered

(2) The plan of treatment must likewise be modified according to the stage of the syphilitic process and the pregnant female with early syphilis is treated in much the same fashion as the nonpregnant one Late syphilis of the heart and aorta may call for a modification of the strenuous antisyphilitic regimen

(3) The length of gestation likewise alters the plan One must realize, of course, that whenever possible treatment should be instituted at the beginning of pregnancy or as soon thereafter as the diagnosis becomes established The patient with latent syphilis who presents herself during the first trimester of pregnancy receives alternating courses consisting of four to six doses of bismuth and eight to ten doses of the arsenical The injections are given at weekly intervals No rest periods are allowed and the last month or six weeks in all patients, irrespective of what plan of treatment is followed, should be occupied with the employment of the arsenical The patient who presents herself during the second trimester is given similar alternating continuous courses with overlapping so that before the series of bismuth is completed the arsenical has been started Whenever possible, in this group the arsenical should be started prior to the sixteenth week of gestation or as close to it as possible In the final group of patients presenting themselves during the last trimester of pregnancy, the plan calls for continuous combined therapy starting, of course, with bismuth as should be done in all cases of latent syphilis Fortunately this last group is becoming smaller

since patients are better educated to the needs of antisyphilitic therapy generally as well as during pregnancy

(4) The presence of mild reactions may call for a change in the arsenical employed in its dosage, or in the co-administration of ephedrine, glucose, or liver extract Severe reactions, however, such as jaundice and exfoliative dermatitis call for a prompt cessation of therapy

In view of the fact that third generation syphilis is possible even though the transmission may not be as frequent as in acquired cases, it is necessary to treat persons with congenital syphilis in a similar fashion to those with acquired syphilis who are clinically latent All patients who have had syphilis, irrespective of the amount of their previous therapy or the results of their serologic reactions, should be treated during each succeeding pregnancy These patients are to be treated as the person with latent syphilis previously described The prenatal patient whose husband is known to have syphilis should not be treated unless a positive diagnosis can be established in her It is well to repeat serologic tests on her serum several times during the course of her pregnancy

What is to be the treatment of patients postpartum? This naturally would depend upon several factors The patient with early syphilis should be treated during her immediate postpartum period while at the hospital, and treatment should be continued after discharge so that no gap in the continuity of her treatment occurs For patients with late or latent syphilis who have received adequate previous treatment no further postpartum therapy is required, but in those cases where previous treatment was inadequate the patient may have a rest period for one month postpartum after which treatment should be resumed It is felt that the risk from this rest period is slight as compared to the necessity for the postpartum patient to accustom herself to her change in routine and habits resulting from an addition to her family In the patient with early syphilis the danger of this rest period is certainly too great to be permitted

The bismuth preparation of choice is bismuth salicylate, 1 or 2 cc of which is given intramuscularly The arsenicals employed, such as arsphenamine, mapharsen, and neo-arsphenamine, are given intravenously When arsphenamine is used, 0.1 Gm. is the initial dose This is increased to 0.2 Gm. and finally

to 0.3 Gm, the latter dose is maintained, and only on rare occasions is this dose exceeded. With neocarsphenamine the initial dose is 0.2 Gm increasing to 0.3 Gm and maintained at 0.45 Gm. Rarely is the latter dose exceeded. With mapharsen, one starts with 0.01 Gm increasing gradually to 0.04 Gm and not infrequently to 0.06 Gm.

Results of Treatment

A total of 566 cases have been studied from the standpoint of the effect of syphilis upon pregnancy and the value of treatment. In this group there were 51 congenital or possibly congenital cases, five sets of twins, and 3 maternal deaths undelivered, 2 of which resulted from reactions with arsenical therapy. This leaves 517 babies delivered of 512 mothers who had acquired syphilis. The 97 babies delivered to mothers who had received no treatment were previously discussed. Treatment given only during pregnancy salvaged 61.9 per cent of the babies while treatment given both before and during pregnancy was capable of salvaging 92.1 per cent of the babies. A disastrous result in this latter group occurred in only 4.1 per cent of the cases, while in the group who received treatment only during pregnancy a disastrous result occurred in 25 per cent of the cases. This high incidence may be explained by the fact that all cases receiving any therapy during their antepartum course only were included, irrespective as to when therapy was started or how much was given. Where treatment was begun before the sixteenth week of pregnancy this figure was appreciably reduced. Naturally as the period of gestation increases before therapy is started, one can expect a proportionate increase in the incidence of disastrous results. However, it is never too late in pregnancy to institute treatment, for some good may still be accomplished even though the disease may have already been transmitted to the unborn child. Where treatment was started any time after the sixteenth week of gestation even in the absence of previous therapy, the incidence of prematurity was reduced to 14 per cent, disastrous results occurred in 29.5 per cent, and 55.6 per cent were salvaged free from the disease. Thus, providing the damage was not too extensive already, late treatment was capable of considerably reducing the death rate, even though babies discharged alive with syphilis did not show any marked reduction, obviously because the disease may

have been transmitted before the institution of therapy.

The Diagnosis in the Newborn

Since the aim in the treatment given the prenatal patient is primarily directed against the transmission of this disease from mother to offspring, the end results are naturally to be judged by the status of the newborn child. Where no treatment had been given and the disease in the mother was of comparatively short duration, gross evidences such as maceration in the stillborn or other skin and mucous membrane manifestations in the live born child are to be observed. However, in those instances where the disease has been of longer duration in the mother or where treatment may have been given though inadequate, visible manifestations may not arise until sometime after the first month or six weeks. Dark-field examination of the umbilical vein scrapings theoretically seems to offer a very valuable diagnostic aid, but unfortunately in our study positive results were obtained in those instances where obvious manifestations in the infant were likewise encountered. Only on infrequent occasions was a positive result obtained where no other gross lesions existed at birth. If any treatment had been given the mother, the results were almost invariably negative.

Since the placenta is the organ through which the transmission of the disease takes place, one would expect it to be the seat of gross and microscopic pathologic changes. The characteristic picture of a syphilitic placenta is most often obtained where syphilitic manifestations are also present in the newborn. This picture may be prevented or altered by therapy given the mother, even though the therapy may have been inadequate to have prevented transmission of the disease. Obviously then, syphilis may be diagnosed subsequently in some infants where the placenta showed very little if any pathologic change. Suspicious changes that might be interpreted as possibly syphilitic changes have been seen in placentas when the infant was free from the disease. Finally, the single pathognomonic finding in the placenta is the presence of spirochetes which necessitates a special and lengthy staining technic and the careful examination of numerous sections.

Positive serologic results on blood from the cord are not pathognomonic of the presence of syphilis in the newborn when the mother's intrapartum serologic reactions are also positive, for there may be a passive transfer of

reagins from mother to child. In most instances these passively acquired reagins are excreted before the first six or eight weeks of life, so that a distinctly positive reaction beyond this period, even in the absence of other clinical findings, must be interpreted as due to the formation of these reagins in the infant as the result of its infection. Were a quantitative complement fixation test employed, such as is done by the New York State Department of Health Laboratories, one might be able to follow by repeated tests during this interval either the diminution or the maintenance of a reaction. In this way a diagnosis may possibly be reached at an earlier date, particularly in those cases where other positive evidences are lacking. On the other hand, a negative test on blood of the cord does not absolutely indicate the absence of syphilis in the newborn, for the infant may develop a positive Wassermann at a later date (although this is infrequent).

X-ray examination of the long bones taken during the first week of life has been of inestimable value in many instances where clinical manifestations of the disease were lacking. The definite changes brought about by an osteochondritis are of pathognomonic value, suspicious changes, however, only warrant further x-ray study after as short an interval as a week. Negative observations may still occur in the presence of congenital syphilis.

Therefore, from what has been said, often no definite conclusion as to the status of the newborn child can be reached at the time of discharge from the hospital. Treatment should be withheld until a definite diagnosis is established. Follow-up studies are essential for a diagnosis. At the return visits physical examinations and serologic tests are repeated and evaluated. X-rays are repeated as indicated. When negative findings are obtained, the return visits are made at monthly intervals until the end of the third month. Where suggestive findings have been obtained more frequent visits may be necessary. After the third month the interval between visits may be lengthened. It is not only advisable but necessary to follow these children in this fashion for at least two years. If syphilis is present, a diagnosis is established in most instances during the first few weeks or months of life. From this period until the end of the second year of life, a few additional cases will be detected. Beyond this period only the exceptional case will develop evidences of congenital syphilis. For ade-

quate follow-up studies, the whole-hearted cooperation of the pediatrician is essential.

If treatment could be introduced early in the prenatal syphilitic patient—that is, soon after the onset of pregnancy or at least prior to the fourth month of gestation—congenital syphilis would become extremely infrequent and perhaps a rarity. This phase of syphilis control brings the most gratifying returns with a minimal expenditure of effort, providing one obtains the cooperation of the patient.

Conclusions

1 The diagnosis of syphilis in the prenatal patient must be made early, and efficient treatment must be instituted if the transmission of the disease from mother to offspring is to be prevented.

2 Such a diagnosis should be based upon a complete history, a carefully executed physical examination, and properly controlled serologic tests.

3 The only reliable history is that of treatment for a previously known syphilitic infection and or the knowledge of a syphilitic offspring.

4 The history of a pre-existing lesion or unexplained disastrous results in previous pregnancies may be highly suggestive but needs confirmation by a physical examination and serologic tests.

5 In 88.6 per cent of the cases, physical examination failed to reveal manifestations, since the disease was clinically latent.

6 While the diagnosis in 24.7 per cent of the cases was based entirely on repeated strongly positive Wassermann reactions, it was of value in a far greater number of instances, since many patients willfully or otherwise withheld information regarding their syphilitic infection until confronted with the positive result of such a test.

7 In other cases the results of serologic tests acted as very valuable confirmatory evidence.

8 The high degree of efficiency of standard serologic tests available today justifies anti-syphilitic therapy for every pregnant woman persistently showing a strongly positive reaction.

9 The treatment of the syphilitic prenatal patient depends upon the absence of medical and obstetric contraindications, the stage of the syphilitic process, the length of gestation, and the tolerance by the patient for the drugs employed.

10 The earlier treatment is instituted the

better the results as far as the offspring is concerned, but it is never too late in pregnancy to do some good by antisyphilitic therapy

I wish to express my gratitude to Dr Miriam B Clark for her assistance in the statistical work-up of this paper

CHILDREN NEED CARE OF GOOD PHYSICIAN—by ANGELO PATRI

Trying to bring up a child of today without the help of a good doctor is likely to end in unrewarded effort. Most mothers need the help of the doctor who knows the child intimately, that is, the doctor who has known him since birth, and before. Very few people cannot find the money to pay for the supervision such a doctor gives a growing family. No money is so well spent as the few dollars paid him for the friendly, fatherly, professional care he gives the children.

Just why people think that money paid the doctor is money regrettably spent is beyond my understanding. "I'd rather give the money to the butcher than to the doctor," said a mother who thought it wise to give her 9-year-old boy steak twice a day. "He won't eat vegetables for me and he likes his meat."

The boy was not well. His color was bad, he did not want to play, he was irritable, and his school work was falling steadily. When we suggested the doctor she said what with meat so high and all she just couldn't afford the doctor. My notion was that if she had held on to her doctor she would not be buying so much meat, her little boy would be eating his vegetables and drinking his milk, getting his ration of meat, and getting along nicely like his classmates.

By and by the doctor had to be called. He regulated the child's routine, gave him a diet list, watched him for a while, and sent him on his way fit and hearty. His bill was \$25 and it came out of the household budget without hurting anybody. The new diet reduced the meat bill, the new routine cut down the movies, and the candy-hot-dog-pop expenses. And the boy was happy and well.

I've seen the same thing too many times not to know that the supervision and advice that a good doctor gives to the family of his patron are worth far more than any money measures. Provision for his yearly fee ought to be made with the same finality as provision for food and clothes, and paid quite as cheerfully. Any family that can dress well, run a car, attend the movies and shows can afford medical attention for the family. That item should head the list of essential, fixed charges. Insurance of several kinds is essential, but the doctor's care should precede them all.

When you find a good doctor for the family, stick to him. Do what he says faithfully. Train the children to trust him as their good friend always. Never use him as a threat or his service as a punishment. His service is farther from that idea than anything you can imagine. His work insures health which is the basis of growth, and success, in any field of life.

And pay him promptly. Doctors are servants to the needs of humanity. They answer the cry of distress at any hour of the day or night. They ease pain, they heal the sick, comfort the suffering, and make the way of death peaceful. Their service is beyond price, spiritually, but doesn't that make us doubly indebted to them? Who would shrink his own soul by withholding a debt for generous, skilled service to his loved ones—or to himself? Your doctor is your ministering friend. Acknowledge him.

DROWNING AND ELECTROCUTION

Teachers of first aid will find useful material in an article by R. T. Payne in the *British Medical Journal* (May 19, page 819), notes *Health News*, from which the following is quoted:

"The victims of drowning and electrocution are in a state of suspended animation.

"In such conditions the ordinary signs of death—namely, absence of pulse, heart sounds, respiration, and reflexes—are completely unreliable.

"In the case of drowning recovery is possible after immersion for a considerable period, even up to half an hour or more.

"In the case of electrocution the period of suspended animation may extend to eight hours or more and yet recovery still takes place.

"In electrical accidents do not be unduly alarmed by the knowledge that the voltage was very high, and do not be reassured by the knowledge that the voltage was relatively low.

"In all cases treatment must be immediate and on the spot. Seconds may be valuable.

"Treatment must be by artificial respiration, which must be immediate, prolonged, and persistent, and until natural breathing occurs.

"The type of artificial respiration employed must be determined by the nature of the accident, the skill, ability, and experience of the resourer, and the presence of complications.

"The first-aid methods of resuscitation can be applied by a medical man, a first-aid worker, or a trained workman.

"The methods of resuscitation which have been described are also applicable to asphyxia following poisoning by carbon monoxide or car fumes, etc., and to asphyxia following an overdose of drugs.

"In all cases in which artificial respiration has been successfully carried out the victims must be guarded from subsequent complications by adequate care and nursing."

VENEREAL DISEASE PROPHYLAXIS

An Ideal Prophylactic and Technic

IRWIN I. LUBOWE, M D, New York City

THE control of venereal disease incidence is greatly influenced by the correct use of genito-infectious-disease prophylaxis. In order for a venereal disease control program to be effective it must include prophylaxis. The conference on Venereal Disease Control Work which met in Washington in December, 1936, passed a resolution to the effect that prophylaxis should be an integral part of each program.

We know that prophylaxis is, in the large majority of cases, effective and successful when used in the Army and Navy because it can be supervised and made obligatory. The soldier or sailor who neglects to safeguard himself promptly after exposure and later contracts a venereal infection because of such laxity is subject to severe discipline.

With the great increase in the Army population and the mobilization of young men as a result of the Selective Service Act, a great many Army camps are being established throughout the country. Experience has taught us that the incidence of venereal disease achieves a new high when so many unknown young men in the Army and Navy are exposed to a possible venereal infection.

On the other hand, prophylaxis among the civilian population can be neither supervised nor enforced. The experiment of maintaining prophylactic stations in civilian communities has been tried but without much success. Civilians, unfortunately, suffer from a misguided sense of modesty in such matters and, therefore, hesitate to avail themselves of prophylactic facilities that are in any sense public.

Therefore, it is essential that civilians be instructed as to the value and importance of proper prophylaxis and receive clear, complete information as to accepted methods of procedure.

Dr. Joseph Moore,¹ in the *United States Public Health Bulletin*, divides prophylaxis into four classifications—namely, social, chemotherapeutic, mechanical, and chemical.

The social prophylaxis may be influenced by means of law or aided by educational, social,

and religious agencies. However, the personnel of these organizations must be instructed and correctly informed by capable and skilled physicians who possess accurate and modern scientific knowledge of venereal disease.

The general public must realize that every illicit sexual exposure is a potential risk of acquiring syphilis, gonorrhea, or chancroid. The surest means of avoiding infection is, of course, sexual abstinence. However, each individual must be guided in his sex behavior by the dictates of his instincts and the routine of his personal life.

The medical methods of prophylaxis are those with which we are closely concerned, and it is these methods which may be subdivided under the terms chemotherapeutic, mechanical, and chemical.

In the chemotherapeutic prophylaxis three methods are suggested—namely, (1) the oral use of a pentavalent arsenical before and after exposure, (2) intramuscular injection of bismuth during the period when exposure may occur, and (3) the intravenous injection of arsphenamine derivatives after exposure.

The oral use of arsenicals is condemned because of its toxic action, and there is no experimental proof to indicate its efficacy.

Bismuth prophylaxis has been found to be of some benefit when used by professional prostitutes. However, its use as a prophylactic in ordinary practice of medicine is not feasible.

The suggested use of arsenical prophylaxis² intravenously has so far been limited to individuals who have come in contact with a known syphilitic. The value of this procedure in man is still dubious, especially since to be effective the arsenical must be given in large therapeutic doses. Furthermore, it is toxic and may cause anaphylactic reactions. Some physicians believe that this procedure may merely suppress an infection, with the possibility of visceral, cardiac, vascular, and neurosyphilis manifestations in the future. The present status of chemotherapeutic prophylaxis is one of doubt and uncertainty, and these mediums are neither accessible nor practicable to the average adult.

At the present time, one hope of venereal disease prevention lies in mechanical prophylaxis.

¹Delivered at the American Neisserian Medical Association Meeting June 10, 1940.

²Clinical assistant, Department of Dermatology and Syphilology, Metropolitan Hospital, and medical inspector, Bureau of Preventable Diseases, New York City Department of Health.

laxis This is a simple, inexpensive, comfortable, and effective protection against all venereal diseases for both sexual partners simultaneously It consists merely of the use of a rubber sheath, which is applied by the male over the penis Some of the disadvantages are that it is considered abnormal and detracts from the full and complete sensation which should be experienced during intercourse There are various types, textures, and qualities of condoms in use However, since at the present time there are no definite standards for testing the effectiveness and quality of these devices, a great number of manufacturers have placed inferior products on the market The state of Oregon was the first state to set definite standards of quality in the production of condoms, and we believe that in the near future carefully prescribed rules and regulations for the quality of rubber sheaths will be established in every state in the Union, thereby assuring the user of really dependable prophylaxis

By chemical prophylaxis is meant the application of medicaments to those tissues which have been exposed in order to prevent the penetration and growth of organisms in the genitourinary apparatus We know that chemical prophylaxis,^{3,4,8,11} if used early and according to proved procedure, will in the majority of cases prevent the acquisition of venereal disease The technic of prophylaxis as developed in the United States Army and Navy is as follows

After sexual exposure,⁵ the patient first urinates, then the genital organs, including the adjacent surfaces of the thighs, are thoroughly washed with tincture of green soap and water Special care must be taken to lave the meatus, the glans penis, the frenum, and the foreskin. After the parts have been dried, the next step is to inject into the urethra (with a B-D urethral syringe) 1 drachm of freshly prepared 10 per cent argyrol or 2 per cent protargol The solution is retained within the urethra by the application of pressure over the glans penis with the forefinger and thumb, remains in situ for five to ten minutes, and is then allowed to exude gently from the meatus The next important procedure is the introduction into the urethra of $\frac{1}{2}$ to 1 drachm of 33 per cent calomel ointment, followed by the vigorous inunction of the preparation into all parts of the penis—namely, the glans, the frenum, the prepuce, and the scrotum The genitals are then encased in a cloth bag, which is either tied around the shaft of the penis or in some cases held in

place by a string around the waist The ointment is permitted to remain in contact with the exposed parts for several hours On the following morning the salve is thoroughly washed away

The formulas for prophylactic ointments used in the United States Army and Navy are as follows⁶

UNITED STATES ARMY		UNITED STATES NAVY	
	Parts		Parts
Hydrargyri chloridum		Calomel	33
mita	30	Camphor	2
Adeps benzoïnatus	65	Phenol	3
Cere alba (U S P)	5	Anhyd. lanolin	39
		Benz. lard	20
		Beeswax	3

At this point, it is interesting to note that Dr R. C. Boyden,⁶ of the United States Navy, after a careful study of the methods of prophylaxis used in China concluded that the most desirable method was a combination of the injection of silver salts together with the application of a mercurial ointment in contradistinction to the use of an antiseptic ointment alone Dr Boyden was of the opinion that the use of ointment alone created a false sense of security, and he cited a number of known cases of syphilis which were acquired despite the careful use of prophylactic "tubes"

Dr Wolbarst⁷ states that it is agreed that while the calomel ointment in the commercial packages protects against syphilis it is not equally effective against gonorrhea Solutions of silver, if injected into the urethra, are much more effective when used with the calomel ointment However, Lieut Comdr J R. Phelps,¹² of the United States Navy, in discussing the use of solutions of silver salts, states that men avoid prophylaxis because these solutions employed cause much more pain and are easily irritating to the mucous membrane, occasionally there follows a non-specific chemical urethritis

At the present time the use of chemical prophylaxis is still empirical There are a great number of tubes available which are not definitely preventive in action but merely possess antiseptic qualities to a minimum degree

The United States Navy insists upon the following formula $33\frac{1}{2}$ per cent calomel, 3 per cent phenol, and 2 per cent camphor By repeated laboratory examinations Dr Robert A. Bachmann⁷ has shown this formula to be not so powerful antiseptically as might be desired It yields only 4- to 5-mm rings by the agar plate test as required by the United States Department of Agriculture,⁹ and Dr Bachmann is of the opinion that the agar yield should be 7 to 10 mm. and should, under

examination, show sufficient strength of diffusibility to be used also as a preventive against the growth of gonococcus

In the Army and Navy¹⁰ the use of a solution of silver precedes that of calomel ointment, which necessitates two distinct and separate operations. The introduction of an ointment in a special base which will add to its ease of diffusion as well as its absorbability and which also contains the proper antiseptic substances would be an ideal contribution to the field of prophylaxis. We thought it highly practicable and desirable to combine mercury and silver in a colloidal state suspended in a stearate and cholestrinized benzoated cream base. The value of colloidal mercury and silver is recognized, and their advantages over the commonly used crystalloid organic and inorganic chemicals are known to physicians and chemists.

Antiseptic studies on agar plates have shown the colloidal mercury and silver ointment to possess a high phenol coefficient.

Report of bacteriologic examinations of colloidal silver 0.05 per cent and colloidal mercury 0.2 per cent in ointment form*.

Resistance of test organisms to phenol shows the following

	1 Minute	3 Minutes	5 Minutes
1-60	0	0	0
1-80	+	+	0

Two methods were used in testing the antiseptic properties of the ointment.

In the first method, known as the "Surface Method," the organisms were transferred from a heavy liquid culture by means of a sterile swab to the surface of the medium, and streaks were made from the periphery inward toward the center of the plate. A central disk was removed from the agar, leaving a hollow for the reception of the ointment to be tested.

In the second method, or "Deep Method," the ointment was tested to show its penetrative effect upon the organisms that had been

FIG 1 Agar plate of 0.5 per cent colloidal mercury ointment, showing an inhibitory zone of 12 mm with *Staphylococcus aureus*.

diffused throughout the agar medium. To melted agar at about 42 C, about 0.4 cc of *Staphylococcus aureus* hemolyticus was added. This was poured into a Petri plate. A disk approximately 1.5 cm in diameter was excised from the center of the hardened agar medium. The hollow was filled with the colloidal preparation and incubated for forty-eight hours. Observation after the incubation period showed a clear zone of 11 mm, and excellent diffusion and penetration were demonstrated.

The same tests were performed in dilutions of 1:5 and 1:10 by both the Surface method and the Deep method. It merits remark that the inhibitory zone of the 1:5 dilution was larger than in the undiluted form. This is probably due to the colloidal silver and mercury particles being readily dispersible in the liquid, thereby releasing their latent potential diffusive and antiseptic properties.

These examinations show the ointment to possess distinct and marked antiseptic properties as indicated by the clear zone on the agar plate. Even beyond this clear zone for a radius of 3 to 5 cm, very few colonies of the test organisms were present, whereas beyond this outer zone many colonies of *Staphylococcus aureus* grew, indicating that there were many viable organisms present (see Figs 1, 2, and 2A).

* This antiseptic ointment known as Pro-col was furnished by Colloidal Laboratories of New Jersey.

Method used	The agar cup method of the United States Food, Drug and Insecticide Administration, Method of Testing Antiseptics and Disinfectants
Medium used	Nutrient agar containing peptone 1 per cent, beef extract and agar
pH of the medium	7.4 to 7.6
Amount of the medium to the plate	20 cc.
Test organisms	<i>Staphylococcus aureus</i> hemolyticus taken from a fresh abscess
pH of the ointment	1-10 dilution of 8.2

Fig 2

Fig 2 Agar plate of 0.05 per cent colloidal silver and 0.2 per cent colloidal mercury ointment, showing an inhibitory zone of 10 mm with *Staphylococcus aureus*

Fig 2A

Fig 2A Agar plate of 0.05 per cent colloidal silver and 0.2 per cent colloidal mercury ointment, showing an inhibitory zone of 12 mm with *Staphylococcus aureus*

It is a well-known scientific fact that colloids are activated when taken internally or coming in contact with tissues of the human body. The concentration of the colloidal mercury is 0.2 per cent and that of the silver used is 0.05 per cent, which is a comparatively dilute percentage but nevertheless gives a valuable antiseptic reaction when observed in the agar plate method. The ointment was found to have diffusion and penetration. Animal and human experimentation has proved it to be stable, antiseptic, and non-irritant to the mucous membranes. Pain is not experienced in the urethra after urination several hours after the prophylactic tube has been used.

This ideal venereal prophylactic is one that can be easily applied and possesses antiseptic properties that inhibit the growth of the gonococcus organism and the *Spirochaeta pallida*. At the same time it is neither painful nor discomforting in its administration. The use of soap and water after intercourse, as a preventive measure against the growth of gonococcus and chancroid organisms is highly recommended. Frequently, however, due to inconvenience and embarrassment, the use of a cake of soap and accompanying sanitary measures may be deliberately neglected. We therefore

decided that the availability of the gauze pad soaked in tincture of green soap or a sulfonated soap, which by simple moistening can be converted into a complete cleansing agent, would facilitate the conscientious use of the entire prophylactic technic.

The germicidal superiority of a colloidal mercury and silver ointment over the previously used calomel preparation has been proved by these results. By augmenting the chemical superiority of this new formula with the mechanical availability of a cleansing agent, we feel that a simplicity and effectiveness of technic have been achieved in venereal prophylaxis which will go far to minimize the incidence of genitoinfectious disease.

FOLKS, I GIVE YOU SCIENCE!

Scientist discovers new chemical curiosity called Dry Water —News Item

Now Science is a dandy thing—explaining, as it can,

The ultra ray, the Milky Way, and prehistoric man,

Supplying dope on dopes, as well as dope on protoplasm,

And helping rid a dog of fleas, when as-and-if he has 'em

Yes, Science is a dandy thing, it simplifies invention,

Advances understanding of an nth-nth dimension, Concocts a law of gravity that governs bird and beast,

Says which is north and south and west—and, therefore, which is east

Again, it wields a magic wand in diagnosing ills,

In easing varied aches and pains with ointments, salves and pills,

It tells us how electric current lights a little lamp,

And what the watt is all about, and what the ohm, and amp

Yes, Science is a dandy thing, and now it lets us know

That Wet is not the only kind there is of H₂O, And so, with water on our minds (a sort of arid brain-juice),

Let's drink a toast to Science here—in good old-fashioned rain-juice!

WINNING THE FIGHT ON CANCER

The American College of Surgeons announces that there are 36,078 five-year "cancer cures" in the United States

These are persons who had cancer and who, five years after treatment, are free of the disease. The number is an increase of 6,000 over the total counted three years ago when the college took its last formal cancer census.

The figures are issued as evidence not only that cancer is curable but that the number of persons cured is rising notably. The first census in 1931 showed only about 20,000 five-year cures.

The census was issued on the eve of the surgeons' annual five-day meeting in Chicago. The college also announced approval of 345 institutions in the United States and Canada as cancer clinics.

In proportion to population, New Hampshire stands first in the United States in number of these approved cancer clinics. It has one clinic for each 10,000 persons. Second comes all the rest of New England, and North Dakota, where there is one approved clinic for each 100,000 to 200,000 persons.

Seven states, Nevada, New Mexico, Oklahoma, Arkansas, Idaho, Wyoming, and South Dakota, have no approved clinics. Officers of the college made it clear that lack of an approved clinic did not mean that there was no satisfactory cancer treatment available. Individual cancer specialists, it was explained, did good work in many cases where they did not have the added advantages of group clinics.

TRAFFIC ACCIDENTS AND KIDNEY INJURY

Modern high-powered automobiles and America's superhighways with their terrific accidents have brought perplexing problems to the early recognition of injuries to the urinary tract, Dr James C Sargent, Milwaukee, declares in the J.A.M.A. for September 7.

"The main run of these urinary tract injuries," he states, "are quite symptomless and obscure on admission. Indeed, so obvious and commanding are the symptoms of the other accompanying injuries and so silent are those of the kidney or bladder that important hours are often lost unless the prompt discovery of kidney or bladder injuries is assured through the routine inspection of the urine to note the presence or absence of blood in all accident cases at the time of admittance."

Without such a routine, followed by x-rays, which define the exact injury if blood is present and which suggest proper treatment, Dr Sargent maintains, "the patient with a fractured pelvis may go many hours before her ruptured bladder is discovered or the man unconscious from skull fracture even bleed to death from an unsuspected kidney injury."

COUNTER PRESCRIBING, A FEDERAL OFFENSE

It is worth every doctor's time to study thoroughly the provisions of the new Federal Drug and Food Act. The act is now in effect and places significant restrictions on the dispensing of drugs, particularly by the pharmaceutical profession. Drugs like the barbiturates and sulfanilamide are specifically restricted in their sale, and, providing the druggist obeys the law, counter prescribing of such dangerous medicaments is definitely hampered.

Not only the druggist, but the doctor who dispenses these drugs from his office, is affected by this regulation. Physicians who dispense drugs must go to the trouble of making the complete name, dose, and other pertinent information on the package before giving it to the patient. Whether this portion of the law will be rigidly enforced must be proved by time, but it is well to note it is now a Federal Act that compels one to do so, and can be enforced.

Gone are the days when samples may be dispensed with careless abandon.

SYPHILIS AND DIABETES MELLITUS

A Critical Study of Their Relation to Each Other in 1,000 Cases of Diabetes Mellitus

JOHN R. WILLIAMS, M D, Rochester, New York

THE recent and renewed interest in the problem of syphilis and the continuing and growing importance of diabetes raises again the question of the relationship of these two important maladies. This topic has afforded a theme for discussion for many years and the literature abounds with articles. The earlier published studies on both diseases were faulty and inconclusive because the reported cases were not adequately controlled. Laboratory technic had not reached the stage of practicality and accuracy necessary for convincing diagnoses. To lesser extent general clinical study of these two important diseases did not receive the careful critical consideration which they are now given. Out of the mass of literature on the subject the comprehensive papers by Labbe and Toufflet¹ and by Lemann² are the most noteworthy. Joslin³ summarizes the known facts and records his own experiences in a well-written chapter in his manual which brings the subject up to date. There is a unanimity of opinion among these authors that there is little evidence of a causal relationship between syphilis and diabetes and that the former is rarely a clinical factor in the treatment of the latter. I have carefully read most of the articles that have been published since 1920 and am of the opinion that little is to be gained by detailed reference to them. Numerous case reports of very questionable scientific value have appeared. Other articles from investigators of note are patently in error. The more authoritative studies support but add little to the conclusions of Labbe and Toufflet and Lemann. The recent literature is comprehensively and fairly considered by Lemann so that further reference to previous writing will not be made.

In this study I wish to restate some of the important questions which constantly arise and to answer them in the light of my own experience. Before proceeding to a discussion of these questions, it would be well to define the terms employed. What is meant by diabetes? In many published studies, diabetes

is any condition wherein a reducing substance to copper salts is found in the urine. In some instances the diagnosis has been based on excessive urination associated with loss of body weight. What is syphilis? Here is an even greater opportunity for error. Many of the statistical diagnoses of syphilis are based solely on positive or even doubtfully positive Wassermann tests.

True pancreatic diabetes, which is being considered in this report, is a deficiency disorder dependent upon pancreatic dysfunction. It may be influenced or modified by an associated disturbance in the pituitary body, the suprarenals, or the thyroid. There is clearly a measurable disturbance in glucose metabolism with a definite relation between food intake and urine sugar outgo in true pancreatic diabetes, whereas in many of the states that are confused with this disorder no such relationship exists. It is because of the inclusion of such faulty data that many of the published studies are of limited worth.

In the evaluation of any therapeutic procedure or test of diabetes, the following factors must be borne in mind:

- 1 Diabetes is a rapidly progressing disease process in the young and is difficult to control. In the middle-aged and elderly, the converse is true.

- 2 Acute diabetes or diabetes of recent onset at any age responds readily to both dietetic and insulin therapy for several months to a year. In the young, it then becomes a retrogressive process, in the middle-aged and elderly, it may remain at a fixed state or become less severe.

- 3 If these facts are disregarded, conclusions as to therapeutic procedures may be worthless. Many a remedy for diabetes has been acclaimed and advanced as having definite value because the observed clinical improvement was mistakenly attributed to a given remedy, whereas it has been due to the natural processes of physiologic adjustment.

- 4 Furthermore, in the study of diabetes the criteria by which progress is measured are frequently faulty. Diabetes is a disorder characterized by deficient glucose

From the Department of Medicine, School of Medicine and Dentistry, University of Rochester, and the Medical Clinic of the Strong Memorial and Rochester Municipal hospitals.

metabolism in which there is a definite relation between food intake and urine sugar output. Ultimately, all of the excessive or unutilized food sugar in the body is either burned or stored to be used later. This physiologic process may take place in one day or it may occupy several days. If these statements are true, it follows that conclusions based on inaccurate diets and casual qualitative urine sugar examinations are grossly inaccurate methods of measurement. Yet these are the methods that are most frequently employed in the study of diabetic therapeutic procedures. The limitations of this paper will not permit a further discussion of this point. Sufficient to say that in any study of this sort only old, tried, and tested cases, whose glucose metabolism is fixed, should be used. The food intake and glucose utilization should be studied with methods of accuracy over periods of several days. The blood sugar level is not a measure of glucose metabolism and, if relied upon as an index to therapeutic procedure, will give grossly misleading results. I have treated this subject of the criteria for the interpretation of diabetes in another study soon to be published.

Even more difficult than diabetes is the interpretation of the clinicopathologic phenomena associated with syphilis. Among physicians generally, and in some clinics, the presence of a single positive blood Wassermann is accepted as *prima facie* evidence of syphilis. While it is probably true that the majority of individuals who show a positive serologic test have or have had syphilis and that the test, therefore, has serious import, it is by no means to be accepted unconditionally as conclusive evidence of existing active or even latent disease. Moore⁴ in the early chapters of his manual discusses in detail and supports this point of view.

Not infrequently the doubtful tests familiarly designated as 1 or 2 plus are accepted as evidence of syphilis. Experts in the field of syphilology, of course, are thoroughly familiar with the significance and limitations of the Wassermann test, but this cannot be said of general practitioners and many medical authors.

A brief résumé of the recent teachings regarding this important laboratory procedure may not be amiss.

1 A 4 plus reaction to the commonly employed antigens means that the blood under test contains the minimum titer of antiserums to justify the conclusion of a

definite syphilitic response. The titer may run far higher than the indicated minimal response of 4 plus, indicating a very strong reaction. If the titer is less than the accepted minimal response, however, it means that the reaction is so feeble as to be of doubtful significance.

2 The Wassermann reaction is more strikingly evident in the young and in the active stage of the disease. It tends to disappear with advancing years. It is frequently present in individuals in whom the syphilis is a healed lesion and in whom no clinical or anatomic evidence of the disease can be demonstrated. The question of what is and what is not a syphilitic lesion is still a matter of controversy among pathologists. It is freely recognized that certain unusual disease states and acute infections may give rise to reactions that are indistinguishable from the accepted Wassermann test. The institution of vigorous antisyphilitic treatment on the basis of the Wassermann test alone is a questionable procedure and fraught with dangerous possibilities.

Severe diabetics, that is to say, those patients with low carbohydrate tolerance requiring large doses of insulin and whose metabolism is difficult to adjust, frequently show subpositive Wassermann reactions with one or more antigens. This condition is inconsistent and seems to vary with the nutrition of the patient. In this series there are 23 such cases. Antisyphilitic treatment for these serves no useful purpose and is usually upsetting.

To determine the significance of the Wassermann test in the absence of clinical evidence of syphilis, a study was made of the records of the Strong Memorial Hospital. From 1926 to 1936, inclusive, 312 patients were found to give a 4 plus blood test on one or more occasions. None of these patients presented any historical or physical evidence of syphilis, although in a few instances its possibility was conjectured. Of these 312 cases, 14 died and came to autopsy. The technical procedure of the pathologic department is as follows. A careful inspection is made of all of the organs of the body, following which a routine histologic examination is made of the various tissues. By this technic, these 14 cases presented no anatomic evidence of syphilis, disease and death being ascribed to a variety of causes including carcinoma, aplastic anemia, erysipelas, pneumonia, and other infections. These individuals may have had syphilis at

some time, but it was not a factor in their terminal illness nor was it apparent at autopsy. This limited observation supports the opinion that the Wassermann test is not conclusive evidence of the presence of either active or latent syphilis. Inferences based upon the interrelationship of syphilis and diabetes should be supported by other evidence than the Wassermann test.

As to the influence of syphilis on the course of existing diabetes, it might be well first to consider the influence of infections generally on the disorder. Physicians have long known that infections of one kind or another may be serious complicating factors in diabetes. Likewise, it is known that infections vary greatly as to their seriousness as a complication. The same type of infection may affect different patients in widely varying degrees. For example, a simple cold in one case may be unimportant, whereas in another it may greatly upset the glucose metabolism. The same may be said of carbuncles and pneumonia. As a rule, localized infections, unless severe, have little or no effect on diabetes. At this time it may be well to observe that acute infections of any kind have a greater influence on glucose metabolism than do purely degenerative lesions such as sclerosis, except those which involve the pancreas.

In the light of these observations we may now consider syphilis as a complicating factor. If the disease is to affect the diabetic state, it should do it either in the stage when it is a generalized inflammation or when the syphilis directly attacks the tissues responsible for the metabolic failure. Syphilitic disease is rarely characterized by severe temperature reaction. Except for the transient skin and gland lesions it is usually exhibited as a fibrosing and sclerosing process involving the vascular and central nervous systems and is benign in character and insidious in symptom complex. The important variation from this is the rare, acute, inflammatory, explosive reaction of the visceral gumma of the tertiary stage. But this particular lesion to cause diabetes would have to involve the pancreas. The rarity of syphilitic pancreatitis, excluding congenital syphilis, is indicated by the fact that in the approximately 4,800 necropsies that have been performed in the Strong Memorial Hospital not a single case has been discovered.

With the foregoing conditions and criteria in mind, I attempted the study of the significance of syphilis in 1,000 clearly established standardized cases of diabetes mellitus. Each

of these patients was examined clinically for syphilis and had one or more blood Wassermann tests made. It is interesting to note that in the selection of these 1,000 cases of definitely proved diabetes it was necessary to reject 275 patients who had a questionable metabolic disturbance, so that they are classified as patients with doubtful diabetes. In many published reports on this subject, the inclusion of these doubtful cases introduces a positive factor of error.

The data bearing on syphilis in the 1,000 patients suffering from diabetes were as follows:

Cases showing a 4 plus Wassermann reaction to two or more antigens	20
Cases showing Wassermann reaction less than 4 plus or affecting only one antigen	23
Cases showing positive clinical evidence of syphilis and positive serologic tests	17
Cases in which diagnosis of syphilis is probable but not clearly proved	9
Cases in which diagnosis of syphilis is based on doubtful Wassermann reactions and questionable clinical data	17
Cases in which the positive and questionable evidence of syphilis definitely preceded the diabetes	17
Cases in which the evidence of diabetes preceded that of syphilis	0
Cases in which there was a lapse of several years between the onset of the syphilis and that of the diabetes	15
Cases in which the evidence of the onset of syphilis could not be definitely ascertained	2

As for the effect of syphilitic treatment on the course of diabetes mellitus, 17 cases were treated, as indicated, by approved methods. Varying degrees of improvement were noted. There were no unfavorable reactions. During these treatment courses, the glucose metabolism of each case was critically studied from the standpoint of glucose utilization, blood sugar levels, insulin requirement, body weight, and general well-being. In no case could it be said that the metabolism of the diabetes was significantly enhanced by the treatment of the syphilis. The detailed data of these studies number many hundreds of daily observations. No useful purpose would be served by publishing the data, they are, therefore, omitted.

Conclusions

1. In a series of 1,000 proved standardized cases of diabetes mellitus, syphilis (active or latent) was demonstrated and treated in 17 instances. This ratio is in accord with the experience of other observers and conforms to the incidence of the disease in the general population.

2 The Wassermann test is a valuable diagnostic aid but by itself is not a conclusive index to the presence of syphilis

3 There is no causal relationship between syphilis and diabetes mellitus

4 Syphilitic pancreatitis in adults is a rare phenomenon

5 The treatment of active or latent syph-

ilis has little or no effect on the metabolism of diabetes mellitus

"DRAFT THE DOCTORS"

The tragic state of unpreparedness that has spelled bitter defeat for the European democracies must not occur here, declares the editor of *Southwestern Medicine*. Medicine must do its part. In case of armed conflict there will be broken bodies to mend, there will be last rites of mercy to perform. There must remain behind those to care for the civilian population. Wars usually bring epidemics—new problems to public health will arise. How well prepared is American medicine?

A number of the younger physicians proudly hold commissions in the reserves of the Army and the Navy. Patriotically they have worked at training problems, trying to better fit themselves for their posts. But so many are needed, and so few have responded. Plans to draft manpower, industry, and money should not omit the drafting of medicine.

Every physician in this country should be drafted, assigned a post at home or in the field, he says. The income of those left at home should be drastically controlled. Any excess over the scale paid the armed services should be pooled for the benefit of those who had to leave often good paying practices for the small remuneration of the armed services.

If there should be no profiteering in industry, neither should there be in the professions! If the younger physicians are to offer their very lives as a pawn to destiny, let the older ones at home at least offer a portion of their monetary gains!

Pretty speeches to the young man leaving a family behind, hoping to support them on the meager salary of a junior officer, are simply not enough. That young man is no fool—he knows that a shattered practice, however good it may have been, will not feed his children. He will rightly resent any attempt on the part of those remaining behind to cash in on his withdrawal from the field. Young men who know they must go at the first call are demanding in growing strength of tone that organized medicine work out and institute a plan fair to all. They say they only want an even break.

The problem is squarely up to organized medicine. And, if our own bodies do not face it, study it, answer it correctly, depend on it that the government of the United States must and will answer it for us.

THE "COSTS OF MEDICAL IGNORANCE"

Ignorance of the most elemental facts of human physiology and anatomy on the part of the masses of our people makes them easy prey for all sorts of cults and nostrum vendors, said Dr. Francis F. Borgell in a presidential address before the Medical Society of the State of Pennsylvania on October 1. This ignorance leads to the ready acceptance of every concept of disease and its treatment as long as it has the appeal of simplicity. The uninformed have visions of perfect health by alkalization, vitamins, laxatives, bizarre diets, health foods, and so on ad nauseam. The average individual has a more comprehensive knowledge of the workings of his automobile than he does of his own body, yet he will call in an expert to cure the ills of his car but is slow to consult the expert when his human machinery fails to perform properly. The basic problem is not the "costs of medical care" but the costs of lay ignorance of medicine.

The truth of this statement can easily be seen. We need but consider the millions of dollars spent on all sorts of cure-alls, self-medication intensively advertised by press and radio. We need but witness the throngs that follow the lures of the Pied Pipers playing the tunes of foot adjustment and goat-gland implantation. The assumption that the masses are clamoring for medical care at the hands of the trained profession but which they cannot secure because they cannot pay the price is not justified in the light of the millions diverted to the coffers of patent medicine concerns, cults, quacks, and charlatans. The continuous battle by the medical profession for legislation intended to protect the people from their own folly and ignorance only emphasizes the point. Intelligent health consciousness is the foundation needed, more than anything else, upon which to build a sound program of public and individual health. Health consciousness will be stimulated in direct proportion to the degree with which this ignorance is dissipated. Herein lies one of the most fertile fields for our public health departments, local, state, or national.

The family physician cannot be eliminated from any program of public health. He must be an integral part to make such programs fully effective. Every move to replace him by impersonal governmental agencies will eventually tend to defeat real better health objectives.

Diagnosis by intuition is a rapid method of reaching a wrong conclusion—*John Chalmers Da Costa, M D*

Lydia had four children named Eemie, Meemie, Minnie, and Edgar—she didn't want no Moe—*Milwaukee Medical Times*

CHRONIC TONSILLITIS IN SECONDARY SYPHILIS— DIFFERENTIAL DIAGNOSIS FROM DIPHTHERIA AND VINCENT'S INFECTION

A Report of 23 Cases

EVAN W. THOMAS, M D , and DAVID H. GOLDSTEIN, M D , New York City

IT IS well known by most syphilologists that secondary syphilis may be the cause of a chronic tonsillitis which in appearance is indistinguishable at times from diphtheria and Vincent's infection. This is not always appreciated by the medical profession. Of 23 cases of severe chronic syphilitic tonsillitis, observed by us from January, 1937, to June, 1939, 20 were misdiagnosed over varying lengths of time by private physicians or clinics prior to their admission to the syphilis wards of Bellevue Hospital.

We have included in this group only those patients who sought medical advice solely because of a severe chronic sore throat. The series does not include those who had injected throats with or without ordinary mucous patches, a condition which occurs in over 50 per cent of patients with secondary syphilis. During the period under consideration there were 419 admissions to Bellevue Hospital for early syphilis. The incidence of the severe type of chronic tonsillitis was 5.5 per cent.

By incorrect diagnoses we mean cases in which the possibility of syphilis was not seriously considered by the examining physician, despite the fact that in many instances a careful search would have revealed other signs suggestive of the correct diagnosis. In some instances syphilis was suggested as the cause of the associated rash, but in none of the 20 misdiagnosed cases was syphilis regarded as the fundamental cause of the throat infection.

In this series, before the diagnosis of syphilis was seriously considered, 4 patients had attended nose and throat clinics at least once, and 1 had attended weekly for over a month before a rash was noted and a Wassermann test taken. Four had been seen by private physicians, and 12 had attended general medical services. In 3 cases the diagnosis was missed by physicians from whom consultations were requested. The institutions

and physicians visited by the patients were widely scattered, and not all of them were located in New York City. Included within the series were several sailors and young men who had attended hospitals or clinics in various cities because of their sore throats.

There were 15 instances of membranous tonsillitis and 8 of the ulcerative or follicular type. The lesions were bilateral in all cases. Marked hoarseness was present in 2 and a history of severe dysphagia was noted in 3. The duration of symptoms prior to diagnosis was under two weeks in 5 cases and from two to three weeks in 4 cases, 12 had symptoms for a period of from four to eight weeks, and 2 had symptoms for over three months. Three patients had been isolated because of a diagnosis of diphtheria and 1 had received diphtheria antitoxin before the discovery of syphilis. On 1 a tonsillectomy was performed which did not cure the sore throat. The diagnosis was not made in this case until the patient complained of sores about the anus. It was then found that he had condylomata lata which were probably beginning when the tonsillectomy was performed, for he gave a later history of itching and soreness about the anus at the time of operation. He attributed his symptoms to hemorrhoids.

By the time the diagnosis of secondary syphilis was established, all but 1 of the 23 patients had a skin rash. The sore throat apparently occurred from a few days to several weeks prior to the rash in 20 cases. Actual chancres were observed in only 3 patients, thus accounting in part for the delay in diagnosis. An additional 4 gave a recent history of genital sores suggestive of initial syphilitic lesions. Three had relapsing secondary syphilis following inadequate treatment for previous lesions. In every case a strongly positive blood Wassermann reaction was found. In only 7 instances were spirochetes suggestive of *Treponema pallidum* actually demonstrated by dark-field examination. In every case, however, the history, the rapid healing of the throats following one injection of an arsenical drug, and the positive blood Wassermann reactions established the diagnosis. Prior to

From the Department of Dermatology and Syphilology, New York University College of Medicine and Third Medical Division (New York University), Bellevue Hospital, service of Dr. Edward R. Maloney.

their admission to Bellevue Hospital, 6 patients had had throat cultures for diphtheria, 3 of which were reported as positive and 3 as negative. One patient was transferred from the Willard Parker Isolation Hospital where secondary syphilis was found, although throat cultures had been reported as positive for Klebs-Löffler bacilli.

In the majority of cases Vincent's angina was the original presumptive diagnosis, in spite of the fact that prior to hospitalization only 2 were reported as having had positive smears for that infection. It is possible that if routine throat smears had been made on our wards more of the series would have shown the organisms of Vincent's angina. It is a well-known fact that fusiform bacilli and spirochetes are frequently found in cases of stomatitis and tonsillitis that are not caused primarily by these organisms. We have found them occasionally in cases of stomatitis due to pellagra as well as in syphilitic sore throats. Rapid cures were obtained in the former cases by the administration of nicotinic acid and in the latter by antisyphilitic drugs.

The diagnosis of syphilitic tonsillitis in most cases seems easy in retrospect, but it must be remembered that there is nothing characteristic about the sore throats of secondary syphilis. They may present any picture from mere enlargement of the tonsils or mild inflammation to deep ulceration or a thick membranous exudate. For physicians unaware of this fact, the throat lesions tend to make them less suspicious of syphilis than they otherwise would be. Even the presence of a rash, especially if it is unassociated with an obvious chancre, may not suggest syphilis. The following case illustrates this.

Case Report

A white woman, aged 20, entered Bellevue Hospital on May 20, 1938, complaining of a sore throat of three weeks' duration. This had become worse in the week preceding admission to the hospital, when difficulty in swallowing, malaise, and feverishness were experienced. A skin rash was noted six days before admission. Her past history indicated that she had never had diphtheria and that her own and her husband's blood Wassermann reactions had been negative four months before the onset of her sore throat. The physical examination on admission to the hospital revealed a dirty white necrotic exudate forming a thick membrane on both tonsils and extending over the uvula. There was no bleeding when the membrane was removed. Small bilateral cervical nodes were noted as being slightly tender. A blotchy red

macular skin eruption was described as being present on the arms and trunk. The temperature on admission was 101 F, but the patient did not appear acutely ill and subsequent temperatures were normal. The blood leukocyte count was 10,800 with 86 per cent polymorphonuclear cells. Direct smears of the tonsils were reported as negative for Klebs-Löffler bacilli and positive for spirochetes and fusiform bacilli. The diagnosis was ulcerative membranous tonsillitis (Vincent's) with diphtheria to be ruled out by culture. A secondary diagnosis of toxic erythema was made, although the possibility that the rash might be due to syphilis was suggested. A routine blood Wassermann test was taken, but the report was delayed for five days. In the meantime two consultations confirmed the opinion that the tonsillitis was due to a Vincent's infection and that the rash was a toxic erythema. Three throat cultures were negative for diphtheria, and on the fourth day of hospitalization, before the blood Wassermann test had been reported, a request was made for an opinion as to the advisability of giving arsphenamine for the Vincent's infection. One of us saw the patient at this time and attempted a dark-field examination of fluid taken from the tonsils. No spirochetes were found, but the diagnosis of secondary syphilis seemed probable. The blood Wassermann test was reported as strongly positive on the following day. She was then given arsphenamine and her tonsillitis healed within three days after the first injection.

As a matter of fact this patient was diagnosed more promptly than most of the others in our series, but it has been reported in detail because it illustrates several features that are important in making differential diagnoses.

1 Fevers in our series were conspicuous by their rarity, though they may occur. Only 5 of the 23 patients had temperatures at any time over 100 F, and only 2 of these reached a level of 103 F.

2 None of the patients appeared acutely ill as in the average case of diphtheria or sore throats due to pyogenic organisms.

3 In every case the throat and tonsillar lesions healed with amazing rapidity after an injection of one of the arsenical drugs. The average time for healing was two to four days. Skin eruptions invariably took much longer to disappear.

4 Even when throat smears are positive for a Vincent's infection, before accepting that diagnosis a blood Wassermann test should always be taken. Had the patient reported above been treated for Vincent's angina with arsphenamine in the absence of a blood Wassermann test, the throat lesions would have cleared rapidly but the diagnosis of secondary syphilis would have been missed.

We are aware that in some cases the diagnosis of secondary syphilitic sore throats is difficult. This report is made for the purpose of raising the index of suspicion of early syphilis in all cases of chronic sore throats. Since we collected these cases, a patient was seen who had attended an ear, nose, and throat clinic for four weeks and had been given an appointment for a tonsillectomy when a routine blood Wassermann test, taken because the patient was a hospital employee, was reported as 4 plus. No evidences of primary or secondary syphilis were found except ulcerative tonsillitis. *Spirochetes* suggestive of *Treponema pallida* were seen on dark-field examination of material aspirated from the tonsils, but they could not be regarded as absolute proof of secondary syphilis. In view of a positive blood Wassermann test and the history of a negative test taken one year previously, the patient was treated for early syphilis with prompt healing of the tonsillitis. No one could possibly have made the diagnosis of secondary syphilis in this man by inspection, but the case emphasizes the importance of taking blood Wassermann tests on every case of chronic tonsillitis of uncertain etiology.

That this is not generally realized by the general practitioner seems evident from the cases reported here, and, in spite of the excellent discussion of the diagnostic difficulties in chronic tonsillitis due to early syphilis given by Stokes,¹ a review of the literature reveals little emphasis of this important clinical entity. In 1935 Brittingham² reviewed 301 cases of early syphilis in which he observed "throat or tonsil disease" in 35 per cent. He states "In most of these patients the tonsils were enlarged and presented dirty ulcerations. In many of them, however, the tonsils were smoothly and clearly enlarged, with very little evidence of other inflammation such as redness. In the former group, secondary infection was undoubtedly present and it would be impossible to differentiate such tonsils from those infected with the streptococcus or the mixed throat infections which are frequently seen in patients without syphilis." While Brittingham's paper is an excellent presentation of the clinical findings, insufficient emphasis is made of the membranous type of sore throat and its similarity to diphtheria. Moreover, while secondary infection may account for the ulcerative type, such infection must be minimized in the light of the prompt healing after arsphenamine.

Stokes has well phrased the caution, in

emphasis of which these cases have been reported, in the following statement "The taking of blood Wassermann tests more frequently, if not routinely on sore throats, especially if they show evidence of chronicity, and the habit of stripping patients for examinations, even for so small a matter as a sore throat, would lead to the detection of a good deal of secondary syphilis in its incipency."

Summary

1 Twenty-three cases of chronic tonsillitis due to secondary syphilis are reported, 15 of which were membranous while 8 were of the follicular variety.

2 A mistaken diagnosis of diphtheria, Vincent's infection, or simple tonsillitis was made in 20 instances.

3 The characteristic features of this entity are discussed, and the prompt response to arsenical drugs is pointed out.

4 It is urged that every patient with a chronic tonsillitis be given a Wassermann test and a thorough examination for stigmas of secondary syphilis.

December 10, 1940. Since this paper was written we have seen on the wards of Bellevue Hospital an additional 19 cases of chronic tonsillitis which fall in the same category as the patients reported above. Two of them had tonsillectomies without benefit before the diagnosis of secondary syphilis was made.

Discussion

Dr. Leon H. Griggs, *Syracuse, New York*—I feel that Dr. Thomas has read an excellent paper on the subject "Chronic Tonsillitis in Secondary Syphilis." I believe that it is true, as Doctor Thomas has stated, that most, if not all, syphilologists realize that secondary syphilis may cause a chronic tonsillitis. Yet it is evident that many errors of diagnosis are made by the profession at large.

During the past several years, the diagnosis of diphtheria has been stressed with excellent results. Almost the first thought in a case of tonsillitis is the question of diphtheria. Next comes the thought of a Vincent's infection. It is impossible to state when the thought of syphilis appears.

During my personal experience of ten years in general practice, I saw 1 case of diphtheria. Yet in nearly every case of tonsillitis I took a culture. I do not recall that I took many Wassermanns.

Dr Thomas' statement, "there is nothing characteristic about the sore throats of secondary syphilis," is an excellent one. I believe that in a case of chronic tonsillitis one should keep in mind the three possible diagnoses of diphtheria, Vincent's angina, and syphilis. I further believe that the differential diagnosis should be aided by laboratory tests. In other words, a culture, a smear, and a Wassermann should be taken at the same visit.

Again, Dr Thomas has stressed the need for more complete physical examination along with taking a routine Wassermann in suspected throat cases.

In closing I will make the plea, often heard, that we raise our index of suspicion of syphilis. This will be needed more in the future when it is probable that a case of early syphilis will be considered a rare disease.

WORKMEN'S COMPENSATION

We have been informed by the Director of Workmen's Compensation of the Department of Labor that many physicians throughout the state are not yet familiar with the amendments to the Workmen's Compensation Law which became effective on July 1, 1940. These were published in the *NEW YORK STATE JOURNAL OF MEDICINE*, June 1, 1940. The attention of physicians practicing under the Workmen's Compensation Law is again directed to these amendments, and they are urged to comply with them.

It should be noted that the C-14 report must now be forwarded to the employer or insurance carrier and the Department of Labor, within fifteen days instead of twenty days as heretofore. This report should be notarized, but physicians are urged not to delay it if a notary is not available. The C-104 form is reportable within forty-eight hours.

The new progress report (C-14) should be sent to the employer or insurance carrier and the Department of Labor in all protracted cases every three weeks. The Law states that the C-4 report should be submitted "when requested" by the employer or insurance carrier, but it is advisable to submit such reports, even though not re-

quested, at regular intervals, in order to familiarize the employer or insurance carrier with the progress of the patient if the medical care continues beyond the first four weeks or so.

Another amendment, effective July 1, 1940, gives to the Industrial Board the right to assess the cost of medical care against a noninsured employer. Physicians treating claimants whose employers fail to carry insurance should submit bills for medical service directly to the Department of Labor, care of the Industrial Board, 80 Centre Street, New York City, and send a copy of the correspondence and bill to this office.

Workmen's compensation committees or boards throughout the state are urged to bring the above changes to the attention of physicians at the regular meetings of the county societies and by publication in local bulletins.

The various forms (C-104, C-4, C-14, and C-27) are available on application to the local county society office. Forms are obtainable by the societies upon application to the Department of Labor, Albany and New York offices. Physicians should not apply directly to the Department of Labor for blank forms.—*David J. Kalish, M.D., Director*

WAR HALTING MEDICAL JOURNALS

How medical science has been affected by the hampering of the interchange of reports of research work, new discoveries, and other advances of the science among the nations is shown by the steady falling off in the number of medical publications being received from abroad by the quarterly cumulative *Index Medicus* and the library of the American Medical Association. Austrian weekly publications used to come every week to ten days. None has been received since early in June. No Polish or Czechoslovakian publications have arrived for many months. Sixteen such publications were dropped from the *Index* at the beginning of 1940.

The notice of the suspension of eleven French medical publications came over two months ago. The last weekly reports from Italy were received

at the end of June. British publications still come with slight delay.

From January to March, 1940, a total of 8,160 publications of foreign origin was indexed. The number dropped to 7,590 from April to June, from July to August 19 to only 3,415, a loss of more than 50 per cent.

A historian of the Thirty Years' War has written that "all culture and science in Germany died under its deadly breath." History has begun to repeat itself in the Old World. The gangsters at the helm of Nazi Germany, comments an upstate paper, the *Jamestown Post*, combating everything international, are crippling medical science by preventing the interchange of the advances made in it by the scientists of the world.

ALUMNI DAY, NEW YORK UNIVERSITY COLLEGE OF MEDICINE

The date of the annual Alumni Day at New York University College of Medicine has been changed from the usual Washington's Birthday to March 21 and 22, 1941, when the Alumni Association is celebrating the one-hundredth anniversary of the founding of the medical college.

The program will begin with a dinner for all the alumni and their wives at Hotel Roosevelt on

Friday, March 21. On Saturday, March 22 there will be a scientific session at the medical school during the morning and afternoon. The program for this will be published later. There will be a luncheon that day in the lounge at the medical school. Dr Nathan B. Van Etten of the class of 1890, president of the American Medical Association, will be the speaker.

THE ROENTGEN TREATMENT OF PATIENTS WITH ADVANCED MALIGNANCY

JOE VINCENT MEIGS, M D , Boston

JUST over one year ago a patient with a tumor mass in the right flank, following removal of a leiomyosarcoma of the uterus two years previously, reported for follow-up and advice as to treatment. Inasmuch as the tumor seemed somewhat movable, an attempt was made to remove it surgically. Consequently, in March, 1939, at the Massachusetts General Hospital a trial was made to remove this mass. At the exploration it was found that the area was compact and slightly movable but that it could not be taken out without probable damage to the right kidney, the large vessels, and the pancreas. The tumor recurrence was much more extensive than at first thought, and no serious attempt was made to excise it. It was considered a satisfactory case for x-ray treatment as the tumor could be well localized and as other cases with leiomyosarcoma had been observed to melt away with this form of treatment. Consequently, treatment was started in February, 1939. A total of 7,700 r was given, and this was considered by Dr. George Holmes as sufficient. For a short time it looked as though some relief was going to be obtained, but in August, 1939, the patient being bedridden most of the time, the pain became so severe that further treatment was advised. This time the patient was sent to the Palmer Memorial Hospital for treatment with their 400,000-volt machine. Here a satisfactory series was given by Dr. Joseph Marks, but finally the discomfort of the patient both from the growing tumor and the treatment became so great that she was sent home. As this tumor was well localized and as it was her only chance for life, the total treatment was large in amount and the result both of the size of the tumor and discomfort from it was poor. In addition, nausea and vomiting and discomfort from the treatment were great. After a short time at home the patient could, with difficulty, go up and down stairs, but she died in October, 1939. It was obvious to all that the treatments had not done the slightest amount of good and that the patient might have had more good days

if no treatment had been given at all. Her right ureter was blocked by the tumor, and a pyelitis recurred occasionally due to the blockage. During the treatment this was not relieved at all.

In May, 1939, a doctor's mother with a hard, fixed tumor mass in the pelvis was seen in consultation. There were no localizing areas, and an accurate diagnosis as to the source of the tumor could not be made. An attempt was made to get a biopsy by making an opening through the vagina on either side of the cervix, nothing but chronic inflammatory tissue was obtained. It felt as though the tumor might be intestinal with extension from the bowel to the bladder. At cystoscopy a roughened area could be seen on the right which was felt to be growing into the bladder from something extrinsic to it. A biopsy was taken that showed undifferentiated carcinoma growing very rapidly, and no guess could be given by Dr. Shields Warren as to the primary source. Because of the hardness and fixity of the pelvis and because of the positive biopsy in the bladder, exploration and operation were decided against and x-ray treatment was advised. The patient was given 7,200 r by the 400,000-volt machine at the Palmer Memorial Hospital. During the time of treatment the patient suffered from nausea, pain, and in every way was exceedingly miserable. After three months of hospitalization it was felt that the tumor had shrunk some and that the patient could be moved to her home. For months the pain was just as severe as ever, and only slight progress in shrinking of the tumor mass was observed. For the past six months the patient has suffered with intermittent intestinal obstruction, progressive loss of weight, and marked edema. She can get out of bed for a few minutes at a time. It has been necessary to give her morphine or one of its derivatives continuously. Nausea and vomiting are constant. The bladder difficulty, pain, frequency, and incontinence have cleared up remarkably. This patient, though now approaching ten months postirradiation and still living, is miserable. It has been necessary to have constant nursing care, and her whole household is now a hospital ward and everything centers upon the invalid. The treat-

Read by invitation at the Annual Meeting of the Medical Society of the State of New York, New York City, May 8, 1940.

From the Massachusetts General Hospital, Palmer Memorial Hospital, and Pondville Hospital.

ment seems to have slowed up the advance of the tumor and prolonged life, but the life as prolonged is not a happy one and the patient's fortitude is a great tribute to her. It is the opinion of us all that it might have been better to have done nothing and to have kept the patient happily narcotized than to have offered her any hope that the treatment would help and to have encouraged her to believe that it might even make her better for a short time. It is probably true that she has lived longer than she otherwise would have, and yet it has been a living death, with the family constantly conscious of her suffering and her steady downhill progress.

Because of intimate contact with these 2 patients, who in hopeless conditions were given x-ray treatment in a hope of helping pain and suffering and perhaps prolonging life, and because of the unsatisfactory results obtained, an investigation has been carried out in an attempt to evaluate the effectiveness and value of x-ray treatment in hopeless conditions.

Material

To make the study worthwhile it was considered necessary to obtain from the various hospitals and x-ray departments at least 100 patients who had inoperable cancer and in whom a biopsy was obtained and the abdomen closed or a group of patients who were operated upon at least a year before and who had a recurrence in the abdomen or retroperitoneal region after the original operation had completely removed the growth, at least as far as the surgeon could tell. Patients who were operated upon and had most of the tumor removed, and in whom the x-ray treatment had been started, were not included in this series. These 100 cases were either primary inoperable ones or recurrences after a year following what was considered a satisfactory removal of the entire growth. (Another series will be subsequently studied of the cases who have a nearly complete removal of cancer and are then given roentgen treatment.) To obtain such a series seemed easy but, when an attempt was made to find the cases, great difficulty was encountered. Frequently, the roentgenologic departments of the various hospitals have inadequate filing systems of treated cases. There are not many. It is interesting that when individual surgeons were asked about the problem each one had a special patient or two who had fared well with treatment but they forgot the large number that failed. It was therefore

considered necessary to find hospital cases in sequence, and so the records of the x-ray departments of the Massachusetts General Hospital, the Baker Memorial Hospital (private wing of the Massachusetts General Hospital), the Palmer Memorial Hospital, and the Pondville Hospital were searched, 100 cases were obtained. Two cases were taken from the Huntington Memorial Hospital. There was no selection of good or bad cases, but all were taken in chronologic order so that a satisfactory view could be obtained.

In this series lymphomas, disgerminomas, and other radiation sensitive tumors were excluded purposely, for they are in a class by themselves and should be discussed separately. One thing that has been learned from this study is the necessity for the x-ray departments to keep more adequate treatment files. A great deal of time was consumed in finding the cases before any study could be undertaken. A follow-up has been instituted that is 94 per cent complete, so that the end result is accurately known. Very little is recorded concerning the amount of roentgen sickness and discomfort during treatment, and only occasionally is there a note that blistering occurred. Frequently, the roentgenologic department notes apparent relief of pain during treatment that does not coincide with the opinion of the surgical notes. Often a short sentence will be found stating that the patient is much better only to find that he or she has died within a week or two of treatment.

This series suggests that there are good cases for treatment and poor cases for treatment. A good case is one that has localization of growth so that the surgeon can show the roentgenologist exactly where to direct the beam when the x-ray can be applied all around about the malignant process. A poor case is one with diffuse intra-abdominal extension of growth so that x-ray treatment can only be given through multiple fields to cover the extent of the lesion. Cases with metastases outside of the trunk of the body are considered "poor cases," and yet some of these have been given full abdominal doses without any treatment of the metastatic lesions. An attempt has been made in this study to evaluate the results of treatment of "good" cases and "poor" cases. These two groups certainly are not absolutely comparable, for one form of treatment can be given to one group while another form must be used in the other group. To fulfill the requirements it was necessary to include many different tumors and lesions,

and there are not sufficient numbers in each group to make the statistics anything but suggestive

In different years different amounts of radiation have been considered adequate, and in a good percentage of these cases our x-ray department does not now consider the treatment sufficient. At the time it was given, however, it was thought to be enough, but subsequent years have disproved it. Such patients should be disregarded and more found to make up the 100. However, it should be pointed out that these patients were sent to the x-ray department and were given treatment, and, if the total treatment of that day is not considered adequate now, it was then, just as today's treatment may not be considered sufficient ten years from now. Therefore, it will always be impossible to write such a paper as this and please everyone. The x-ray department accepted others and could not finish the treatment. That again should not exclude the case, for the case was considered worth treating and the treatment failed. Another paper, a companion-piece to this one, should be written and should include only those patients who had what is now considered sufficient treatment, who took all the treatment, and who have the same type of tumor. This type of paper will be extremely difficult to do, for such a group will not be easy to find. My presentation is of 100 patients accepted by the x-ray department and of treatment started and the results of such treatment.

Reason for Giving Treatment

Certain patients with inoperable malignancy are given treatment because the surgeon feels he can do nothing surgically and yet something must be done. These patients are sent to the x-ray department with the notation of "inoperable cancer" of the stomach, pancreas, ovary, etc., and a request for treatment. The surgeon rarely, and this is important, goes down to the x-ray department and demonstrates exactly where in the patient's abdomen the tumor lies. A cancer of the rectum may be high or low, in the liver, kidney, or the lymph nodes, or a huge malignant mass may be present, but the surgeon simply requests x-ray treatment and the roentgenologist gives it. The department of roentgenology should not accept such a patient for treatment until the surgeon has gone to the department and explained to the roentgenologist who is to treat the patient, where the tumor is, how extensive, and where

treatment should be given. Sometimes treatment is advocated for the "morale" of the patient. It is difficult to open and close the abdomen and tell the family and patient there is nothing to do about it. So because something should be done to boost the "morale" of all concerned, the patient must be told that x-ray occasionally performs miracles and therefore, it should be tried. So the x-ray department gives treatment that as a general rule makes the patient feel worse (nauseated and sick) and in the end does absolutely no good. In another group, treatment is given to relieve pain, and in our series 13 out of 43, or 32.5 per cent, obtained a moderate amount to a good deal of relief. If it will do this, it is worthwhile, yet its relief is at the cost of considerable discomfort from the treatment. This is much more legitimate than using the treatment for the sake of "morale." Treatment for pain in extensive cases should be given lightly and slowly, and, if a result is obtained in a few treatments, perhaps that should be considered enough. The treatment is sometimes given to stop fluid from reaccumulating. Roentgen treatment may prevent the rapid recurrence of fluid the first time, but the second and third treatments may be of no avail. Careful judgment should be exercised in all groups by the roentgenologist, and he should be the one to decide whether treatment should be given or not. He should be the judge as to whether or not to use his "knife" and not the surgeon.

Type of Treatment

In most instances the treatment was given by means of a 200,000-volt machine with nearly similar distances, screening, etc., in all the hospitals. In a number of instances the 400,000-volt machine at the Palmer Memorial Hospital was used and in a few the 1,000,000-volt apparatus at the Huntington Memorial Hospital. Fields varied from 8 by 10 to 20 by 20 and amounts of radiation from 200 to 12,000 r. The 200,000-volt treatment is given at 50-cm distance, 5 to 20 milliamperes, screening $\frac{1}{2}$ mm of copper, each field receives 200 to 400 r per day. The factors of the 400,000-volt treatment are as follows: 50-cm distance, 5 milliamperes, screening—0.9 mm of tin, $\frac{1}{4}$ mm of copper, 1 mm of aluminum, intrinsic filter is equivalent to about 7 mm of copper. Each portal is usually 15 cm square, and 300 r are given daily. The 1,000,000-volt treatment is given at 70-cm distance, 12 milliamperes, 5 mm of lead, with daily exposures of about 400 r. There are variations

of treatment in all hospitals and in different cases, but the above factors are the usual. In this series most treatments were given by means of the 200,000-volt apparatus. It is quite possible that future results will be better now that roentgenologists are becoming more accustomed to higher voltages, but it is doubtful if hopeless inoperable cases will ever be cured, no matter what the voltage and the skill of the operator. It is our duty and the duty of the roentgenologist to choose cases for treatment when chances for relief at least are present. Treatments just to do something for the patient should be condemned.

Review of 100 Cases

In the group studied there were 83 primary cases and 17 patients with recurrent disease. As stated above, primary cases are those in whom nothing but a biopsy could be done at the original operation, and the recurrent cases are those in whom tumor has come back a year after complete removal of the tumor. Twenty-seven were men and 73 were women. The ages were from the twenties to the eighties, with the large majority from 40 to 70, the usual cancer decades. The results are slightly better than expected and are such that instead of condemning x-ray treatment for inoperable disease perhaps better selection of cases and more intelligent treatment might lead to even better palliative results. Eleven of the 100 patients are now living for from six months to nine years. Of these 11 cases, 4 are in very poor health and are obviously going to die soon, leaving 7 cases that can actually be considered as "satisfactory." There are 4 who have survived over three years, 1 for seven years, and 1 for nine years. The 7 satisfactory cases will be presented in brief case reports below. All male patients are dead, the only survivors being women.

Nothing definite could be gleaned from the size of the tumor of 30 patients with large tumors 6 survived, of 4 patients with localized recurrence 1 is still living, three are living of 40 patients with widespread abdominal extension, and of 38 with metastases from a local growth to other areas 3 survived. There seems to be nothing pertinent in the size or extent of the lesion.

The most common lesion treated was carcinoma of the ovary, 39 were treated and 2 or 5 per cent survived, this being worse than the 7 per cent survival of the entire group. This lesion is one of the most common types of malignancy to be treated by x-ray if the lesion is inoperable. Each of us will remem-

ber a "miracle" case where a tumor was removed or partially removed or where metastases were present and after x-ray treatment the patient has lived for a number of years. This is not necessarily the result of roentgen treatment of the cancer but may be due to changes in the ovary, for without doubt the removal of an ovarian tumor is sometimes followed by a regression of metastases even without any x-ray treatment. This may be due to some hormonal influence. If such a patient is treated with x-ray with a good result, great credit is given to the roentgen ray's effect on cancer. It is impossible to say just what these tumors are, but an endometrial type of growth might regress if an ovarian tumor capable of secreting estrin were removed. Patients with malignant papillary cystadenomas live long, frequently without any x-ray treatment. For this reason it is very difficult to evaluate the result in the 2 survivors in the ovarian group, for they might have lived just as long without any treatment.

Of 28 patients with tumors of the large intestine, 19 being of the rectum, none survived. This type of lesion has always been known to respond poorly to radiation, and this group demonstrates that inoperable tumors of the lower bowel are certainly poor subjects for radiation. There were 7 inoperable cases of cervical cancer, both primary tumors and recurrent abdominal masses, and of the group 1 primary case survived. This tumor was in the cervical stump.

One of the most interesting findings is that of 5 cases of cancer of the pancreas, 2 patients survived. Of 1 there is no question about the diagnosis, and the patient is living seven years after treatment. The other is called cancer by the pathologist every time the slide is reviewed, but doubt has been raised by the x-ray department as to the malignancy of the lesion. Inasmuch as this study relies upon the pathologic findings for the diagnosis, this case must be accepted as cancer of the pancreas. These 2 cases will be presented below in more detail.

Four patients with inoperable cancer of the stomach were treated and none survived, as would be expected. There are a scattering of tumors of other organs treated such as cancer of the bladder with the patient dying, 5 patients with cancers of the uterine body with 1 survivor, 1 patient with cancer of the omentum and mesentery (metastatic from the breast) with the patient surviving. Single cases of cancer of the vagina, tube,

prostate, and kidney have no survivors. The good results, therefore, are limited to the ovary, the cervix, the pancreas, the endometrium, and the breast. No general statement can be made, but, as expected, the ovary and other female genital cancers account for most of the survivors, with the pancreas, strangely enough, having the highest percentage of cures.

The pathology of the types of tumors is of no real interest as no particular tumor responded better than any other. Most of the tumors were adenocarcinomas, and 5 of the survivors were in this group. One patient had three different tumors of three different organs, and 2 patients had two different tumors of two different organs.

Of 43 patients who had pain recorded before treatment, 10 (over 23 per cent) obtained relief. An additional 3 obtained some relief. Six patients obtained no relief at all, and in 24 cases it was not mentioned whether relief was obtained or not. In 4 patients treatment was advised for pain alone, not with the idea of checking the tumor but simply to relieve pain. Only 1 of these obtained any result.

In 19 cases fluid was present in the abdomen, and in 9 cases the treatment either prevented or slowed up the reaccumulation of it. This is of considerable advantage and must be remembered when dealing with patients who accumulate fluid.

In 3 patients the treatment was advised to help the patient's "morale," without result either in benefited "morale" or relief from tumor. This reason for treatment is not a good one.

In 3 patients the x-ray department advised against treatment, but it was urged by the surgeon and given. In 10 cases further treatment was advised against, and in 1 the surgeon requested treatment against advice of the roentgenologist. It would seem that the final decision of whether to treat or not to treat should be determined by the roentgenologist and not by the surgeon.

Radiation reaction of which nausea, vomiting, and general discomfort were the most prominent symptoms was present in 40 of the 100 patients. In addition a smaller group had anorexia, diarrhea, tenesmus, skin reaction, weakness, and some had a temperature. Many had multiple complaints, but in those patients with extensive disease practically all complained of radiation sickness so much that it was recorded in the records.

Thirty-five patients had more than one

series of treatment. Six had three series, 3 had four series, and 1 patient finally had nine series. Two of the patients living and doing well had one series each (cervix and ovary), while the others had two each and the breast patient had multiple treatments.

The primary cases who died lived an average of five and nine-tenths months and the recurrent cases nine and six-tenths months, the total number who died lived an average of six and one-half months after the treatment. These results may be considered a success, but who will say that most would not have survived that long even without any treatment? Is it worthwhile to be sick during treatment and survive only an additional six months, most of it in considerable discomfort?

In considering the length of survival of the dead, it is interesting to notice that 6 patients survived less than a week after treatment, 7 survived two weeks, and 9 survived one month. Therefore, 22 per cent of the patients lived only one month or less after the treatment was finished. Surely these patients should not have been subjected to x-ray treatment. Eleven survived two months, making 33 per cent who died within two months. Fifty-five per cent did not live over six months, and 69 per cent died in less than a year. Twelve cases lived from one to four years, and 11 patients are still living, 4 being practically moribund. These figures indicate that more judgment should be used before this treatment is offered to patients. Only seven per cent did well and, except for 2 cases of cancer of the pancreas, are not likely to live beyond five years after treatment.

Thirteen autopsies were done on patients, and in only 1 patient was x-ray reaction noted in the tumor tissue. It is probable that this is an oversight, but it should be mentioned in protocols, for, if no radiation reaction is noted, certainly there can be no value to the treatment.

Adequate X-Ray Treatment

To decide whether or not a modern treatment would improve the results of this series, a group has been selected of those patients who have had what the x-ray departments consider sufficient treatment to affect the type of tumor present. Four thousand roentgens has been set as the so-called minimum of sufficient treatment. Of the living cases with a good result, 1 pancreas case is omitted, for this patient received only 1,600 r and this is not sufficient to have roentgen treatment be responsible for keeping the patient alive.

nine years. One patient living and doing well had 3,600 r given by the 400,000-volt machine. This treatment is considered adequate. Of the 46 patients receiving what can be accepted as a satisfactory treatment, 6, or 13 per cent, responded well. On accepting this as a satisfactory group of cases, it must be admitted that 13 per cent of respectable results in inoperable malignancy by means of x-ray treatment is good. In other words, if sufficient treatment is given, a fair palliative result may be obtained.

The length of life of the sufficiently treated patients is only slightly better than those treated inadequately. Of the well-treated dead cases 32 per cent were dead at two months as contrasted with 46 per cent of the less well treated. Sixty-four per cent at six months were dead, while 70 per cent of the less well treated were dead. At one year 77 per cent of the well treated and 90 per cent of the poorly treated were dead. There really is very little to choose between these two sets of figures, and therefore this method of approach does not prove that "sufficient treatment" will make very much difference in the length of life. It is true, however, that the living cases, including those dying, were—except for a pancreas case—those that have had sufficient treatment. Thus, well-planned and satisfactory amounts of treatment are imperative.

After the history, examination, and amount of treatment of each case were read, the patients were divided into groups of good cases for treatment, fair cases, poor cases, and very poor cases. There were only 6 cases that were considered as likely to produce any result, and, of these 6, 1 responded well to treatment, (a patient with a recurrent mass of endometrial cancer). One had fair palliation, 1 had slight palliation, and 1 had excellent palliation. Among the 3 fair cases, 1 had slight palliation. In the group of 77 poor cases 1 had good palliation, 17, some palliation, 3, a fair result, and the rest, poor. In the very poor cases 1, a patient with cancer metastatic from the breast, is doing very well. In other words, it is not possible to pick and choose the cases likely to do well, but more can be done to select the ones that will do poorly.

Survivors

Seven patients are considered to have responded well enough to support the advocates of roentgen treatment. Of these 7 women, 2 had cancer of the pancreas, both of these

patients have survived over seven years, 1 on inadequate x-ray treatment. It is therefore doubtful whether or not this case actually belongs in this series and whether the same result might not have been obtained without any treatment. This case has been reviewed from the pathologic point of view, and the pathologist reaffirms his diagnosis. If this case were to be excluded because of the excellent result with inadequate treatment, only 6 patients would be living of the 100 that were investigated. That would leave 2 patients with cancer of the ovaries who unquestionably have done well but are far from cured, a breast patient with disease in her vertebra but who responds beautifully to x-ray treatment, a patient with a grade III cancer of the cervix, a patient with cancer of the pancreas, and a patient with a recurrent mass of endometrial cancer that is still present but is smaller and gives no symptoms. In the entire series the only apparently "cured" cases are the 2 patients with lesions of the pancreas, and the diagnosis of cancer of the pancreas in 1 of them is in some doubt. The record is not a brilliant one but better than nothing.

Reports of Successful Cases

Case 1—A. A., a married woman, aged 60, was operated upon in June, 1939, and inoperable pelvic masses were found with a peritoneum studded everywhere with disease. A biopsy showed carcinoma, type undetermined. X-ray treatment was given at the Palmer Memorial Hospital with the 400,000-volt machine. She was given a series through four portals, left lower, right lower, left upper, and right upper parts of the abdomen. A total of 3,600 r was given. She suffered a slight anorexia. She failed to report and finish her series, and she was not strongly urged to do so. Her doctor writes in March, 1940, that she is still "going on her own power." She feels better than she has for a long time. Her abdominal mass is much smaller.

Case 2—J. B. L., a single woman, aged 33, was operated upon in December, 1936, and a malignant, papillary, solid, right ovary densely adherent in the pelvis was found. The pathologic report was malignant papillary cyst adenoma. In January, 1937, she was given 4,800 r through four portals, front and back of the lower part of the abdomen, 1,600 each to anterior and posterior part of the abdomen and 800 each to the right and left lateral areas. In June, 1937, she was in excellent condition. In April, 1938, she had gained 7 pounds. In December, 1939, a large mass was found in the vaults, slightly movable. Some fluid was present. She was examined with a peritoneoscope and later operated upon, and a supravaginal hysterectomy and bilateral sal-

pingo-oophorectomy were performed. The ovaries and peritoneum were completely involved. In January, 1940, she was given about 8,600 r over her pelvis, both front and back, through four portals. A report in April, 1940, says she has gained 7 pounds. She has a good deal of abdominal pain which is not cramp like. She looks well and has a good appetite. No definite recurrence can be felt in the pelvis.

Case 3—M R, a married woman, aged 70, in January, 1932, had an exploration carried out on the common bile duct and pancreas. A small, shrunken gallbladder was found. The head of the pancreas was hard. A biopsy was done, showing adenocarcinoma. A T tube was placed in the common duct. Because the gallbladder was so small, a cholecystogastrostomy could not be done. In February, 1932, she was given 3,200 r through two large fields, front and back, over the pancreas. In June, 1933, this same treatment was repeated. She was not seen from 1933 to 1936 when she came back with the T tube still present. Gentle traction over a period of twenty-four hours eliminated the tube. A month later she was still flowing a moderate amount of bile. In June, 1937, her wound was absolutely healed and she looked extremely well. In June, 1939, she was completely well. She had an excellent appetite, normal bowel movements, and normal color. No tumor mass could be made out. The slides were reviewed by Dr. Tracy Mallory, and there is no question about the diagnosis.

Case 4—J P was a married woman, aged 26. In January, 1929, an exploratory laparotomy was carried out for an abdominal tumor. There was a large mass the size of a melon posterior to the stomach and fixed to the posterior abdominal wall. It had an elastic feel with hard nodules scattered throughout. The common duct was greatly distended, with thin wall. The peritoneal cavity was opened, and the tumor was identified as the pancreas. A small section was removed for diagnosis. A needle was thrust into the center of the growth but no fluid could be obtained. It was beyond the possibility of surgical removal and showed carcinoma with mitotic figures fairly numerous, and undifferentiated epithelial cells. It suggested a primary growth of the pancreas. In January, 1929, she was given nine treatments with the low-voltage machine, an erythema being given front and back, centered over the pancreas, through a 15 by 15 field. In April, 1929, this treatment was repeated. In June, 1930, there was no appreciable change. The tumor mass extended down almost to the umbilicus. In March, 1932, the skin over the treated area was normal. The patient had no complaints. In 1931 she was delivered of a normal child, the low-voltage treatment having no effect upon the baby. She still had a rounded mass in the abdomen. In September, 1935, she looked very well. Apparently there was no pain referable to the tumor mass. There was no

change in size. In October, 1937, she had been well until recently when she had lost 20 pounds. She was referred to the hospital for study and after study a diagnosis of diabetes was made to account for her symptoms. In September, 1938, we learned that the patient's condition was not very good.

Case 5—G S is a single woman, aged 65. This patient was operated upon ten years previously when a carcinoma of the endometrium was removed. Ten months before she was seen at the Baker Memorial Hospital where a large, hard mass, thought to be a recurrent carcinoma, was found in the right side of the abdomen. She received x-ray treatment there, a total of 4,000 r to the anterior and posterior sacroiliac, to the posterior right pelvis, and to the anterior right pelvis in fourteen treatments in April, 1937. A large mass could still be felt in the right side of the abdomen, both by rectum and by abdomen. In February, 1938, she was given twenty-one treatments through three portals, a total of 6,000 r, with the 400,000-volt machine at the Palmer Memorial Hospital. In April, 1940, the patient's condition was excellent. She looked well and felt well. She had no discomfort of any kind. The mass is still present but much reduced in size. There are marked telangiectases over the area of the treated tumor. This is a remarkable case so far.

Case 6—M M is a married woman, aged 64. The patient had a hysterectomy for fibroids in 1925, the cervix being left in place. She bled in March, 1938. She was given x-ray treatment in May, 1938, twelve treatments to the anterior and posterior pelvis, a total of 4,500 r through a 15 by 15 field and 10 by 10 field. She tolerated the treatments extremely well. The pathologic report showed epidermoid carcinoma of the cervix, grade III. In March, 1940, a letter from her physician stated the patient was free of disease for twenty-two months—no evidence of cancer anywhere.

Case 7—E P, a woman, aged 52, had a right radical mastectomy in July, 1932. A diagnosis of scirrhous carcinoma, grade III, was made, with no metastases to lymph nodes. In October, 1933, she was given 2,000 r to the nodes in the right clavicular region and to breast scar. In January, 1935, she had a left radical mastectomy, the diagnosis being carcinoma. In May, 1936, she was given 2,000 r to the left scar. In December, 1936, she had entered the hospital with a large mass involving the duodenum, the mesentery, omentum, etc., and with gastric obstruction. It was necessary to do a gastroenterostomy to relieve the obstruction. In February, 1937, she was given nineteen treatments through a 15 by 15 field, 2,000 r to the anterior and 1,800 r to the posterior epigastrium. She had a moderate erythema both front and back. She has received treatment off and on to the cervical spine, which is involved in metastases. In January, 1938, following treatment

she had much relief, and in August, 1938, the tumor mass was gone, it could not be felt. In April, 1939, she was again in excellent condition. No masses could be felt. In March, 1940, she suddenly had an attack of pain in the sacral region, probably metastatic area. In April, 1940, her physician stated that she had no gastric symptoms and she was in excellent condition except for the fact that her malignant disease is still present in the vertebrae.

Discussion and Conclusions

From the point of view of organs involved in disease it is obvious that the ovary, the uterus, and the pancreas are the most satisfactory. Cancers of the stomach and intestinal tract show, in this series at least, no permanent relief from x-ray treatment. The size and extent of the tumor plays a small role in the possibility of relief. Men did not do well, as none survived. Pain may be helped in a fair proportion of cases, and abdominal fluid may be slowed up or checked in some cases. Radiation reaction severe enough to mention occurred in 40 per cent and should be considered in advising treatment to the patients with extensive involvement.

From this study it is seen that 19 per cent lived a year or longer, therefore receiving satisfactory palliation. This is a sufficiently good percentage to make us consider this form of treatment in all patients with inoperable cancer. In the future, patients should be selected who have definite reasons for treatment, such as an inoperable growth because of position of tumor, a not too extensive growth, and for the relief of pain, fluid, etc. So-called sufficient x-ray treatment did not prolong life in any appreciable amount over patients with less and, in some instances, inadequate treatment. Nevertheless, of the real survivors of this group of 100 cases, all but 1 had had sufficient treatment. This is slightly encouraging if the proper case for treatment can be selected and large doses given. X-ray treatment of the desperately ill patients and patients with extensive metastatic disease is to be deplored. It is much better to avoid the use of radiation in such patients. Life is not worthwhile if even more suffering is to be the lot of the patient. The surgeon should consider the size of the growth and its extent first, consult personally with the roentgenologist, talk the situation over, decide what can be expected from treatment, and then certain patients should be turned down and sent back to the ward for the use of comforting drugs. All patients with inoperable cancer or recurrent cancer must not be

treated, for often more harm is done than good. It is ill advised to say "Inoperable cancer. Send patient to x-ray!"

Discussion

Dr Donald S. Childs, *Syracuse*—I was indeed happy to have read Dr Meigs's paper. I thought it was an excellent paper to bring to this particular group because he seems to be carrying the torch for the roentgenologist.

It is true that what he says in certain spots backs us around a little bit, but his basic discussion is exactly the thing that the roentgenologist has been talking of for years but never getting any place.

The care of cancer, I believe, is not a surgical problem, it is not a medical problem, and it is not a radiologic problem, but it is a combined problem of all existing facilities.

But the way it is applied it becomes very definitely a surgical problem. Then, when everything goes sour it is dumped over into the hands of the radiologist. At least we hear a great deal about the early diagnosis of cancer. Well, I can count on the fingers of my one hand the early cases of cancer that I have seen.

I was interested in Dr Meigs's statement on his primary and recurrent cases. His primary cases he described as those where the abdomen was opened, a biopsy taken, nothing done, and the abdomen closed. In other words, my interpretation of that is that he had 100 per cent potential mortality. And yet he had, I think it was, 7 per cent recovery with radiation.

Now, I do not believe that there is any so-called cancer specialist in the country who is not tickled to death if he can improve his results 5 per cent.

There are several things that I think we ought to go into, and as a roentgenologist I want to bring them out. We hear a lot about the difference between 200-, 400-, and 1,000-kilovolt x-rays. As far as I have been able to find out, there is nobody today who has ever been able to say that for a given amount of radiation there is any increased biologic effect on 200-, 400-, or 1,000-kilovolt x-rays. There is no increased biologic effect.

There is this effect—less back scatter and less skin reaction, and that is about the limit. That is as far as we know today. Tomorrow may be a different thing.

Now, as to that, the important factor as far as radiation is concerned is the rate at which the radiation is given. The amount of radiation, the distance, the filters, the size of portals, and the time—those are the important factors, particularly the rate or the r per minute in which the radiation is given. I must admit that there is some discussion, particularly in the City of New York, on this particular matter. But I feel that it is generally conceded through the country that the r per minute is rather important.

This is a particularly good group to talk to.

about skin reactions If you are going to get results you are going to get skin reactions, and skin reactions mean redness, itching, burning, and blistering

The treatment of those skin reactions never should be in the hands of the surgeon I saw one the other day, a very ambitious surgeon covered a skin reaction over the lower part of the abdomen with adhesive plaster putting one little light layer of gauze underneath it You can imagine what is happening and what is going to happen

We get the greatest roentgen sickness on the patients who are the most apprehensive I have an individual getting a series of treatments who lives in a town about fifty miles away He gets on the train and he vomits all the way to Syracuse He comes in the office and is treated and behaves himself perfectly, and then he vomits all the way home That, according to him and his physician, is roentgen sickness Well, maybe so

I think that the diarrhea and the tenesmus that we get if we are a little ambitious in our dosage at one time should be cut down by curtailing the dosage

Dr Meigs states that Dr Shatsky said 4,000 r was adequate treatment Well, I do not know what he means, and I do not think he does It is like this 4,000 r means that the patient got 4,000 r, but it does not say a thing about how he got it or where he got it, how the portals were and what the distance was, and says nothing about the depth dose It is really the dose that gets to the tumor-bearing area with which we are concerned

As to 4,000 r—take, for example, saline and you give 4,000 cc to a patient. What does that mean? Absolutely nothing You might have washed his face You might have stuck it down his esophagus or given it rectally or intravenously Yet, you gave 4,000 cc of saline The same thing is true when you say that they had 4,000 r It means absolutely nothing until you go along with the rest of the factors

Now, as to this matter of records I think the question of records is very important and everyone knows that they are inadequate in most hospitals The reason for it is that the roentgenologist, by his natural makeup and because of his occupation, is naturally shy, reticent, and easily dominated. The patient comes primarily to the roentgenologist because somebody, somewhere, decided that roentgenology was to be used. The roentgenologist is never consulted as to the advantages of it, either in the diagnostic field or the therapeutic field. Patients are simply dumped in your lap

If you are going to have competent records, you must have cooperation between the clinical departments The personnel of these departments change every three or four months, but the roentgenologists are still around You must have that cooperation, and you must have your consultation about the case (whether it is going to be treated or not) before the patient or the patient's family is told

Again my experience is that the patient is in bad condition and the patient or the patient's nearest relative has been told that the only thing we can do is to give them the roentgen ray

Now, being shy and reticent and all that, what can we do? We cannot do one single thing. We have to treat them

As to the treatment for the morale of the patient, I agree with Dr Meigs It was good to have this opportunity of getting things off my chest in front of a surgical section, and I appreciate the torch bearing that Dr Meigs gave us.

Dr Louis C Kress, *Buffalo, New York*—Dr Meigs today has discussed a troublesome problem and in a measure has given us an answer that does not satisfy us all. His paper deals with a group of patients who were unfortunate in having advanced cancer The type of malignancy encountered in these patients was undoubtedly the differentiated type Pathology, grading, etc., were not considered in this paper, but most of the tumors were adenocarcinoma and in organs in which this type of pathology is most frequently encountered These types do not respond as a rule to radiation, but in spite of this fact he did salvage 2 per cent Without radiation it is fair to assume that perhaps 1 per cent of these would have succumbed to the disease The other 5 per cent did have their lives prolonged, which perhaps was or was not a benefit to the patient depending on the point of view that one assumes

It cannot be ascertained with absolute certainty how a given tumor will respond to radiation until this therapeutic agent has been applied. The chance is worth taking A doctor's wife came under my observation with a hopeless inoperable carcinoma of the rectum. It was radiated, external radiation and radium being applied to the tumor She is alive and well today—twelve years after treatment A competent pathologist confirmed the clinical diagnosis. This is the exception yes, but if it occurred to a member of one's family it would be much worthwhile

It is generally accepted that radiation has no effect on carcinoma of the stomach (lymphosarcoma excepted), that it does at times afford palliation, but that in the end it does cause the patient to suffer longer This also holds true for lesions of the large bowel At times the radiologist is called upon to treat these patients, and it is difficult to refuse, although the judgment of the radiologist is to the contrary

Dr Meigs's plea for better records is well taken. The factors concerning radiation therapy are usually recorded, but the clinical progress notes are at times lacking In our program in New York State we are endeavoring to encourage our clinics to keep adequate records so that they may be used for study at some future time.

Cancer therapy is not a one-man job but should be done in consultation not only with the radiologist and the surgeon but also with the pathologist The pathologist can at times give valu-

able information as to the therapeutics that should be followed, the parts of the body to be treated, etc. A radiologist should exercise his right as a doctor and make a thorough examination of a patient before the patient is treated. Too many radiologists are no longer clinicians, but they should never side-step the opportunity to examine a patient. This makes for more interesting and thorough radiology.

Radiation sickness has been mentioned several times—some patients have it, others do not. There are no means to my knowledge of telling which patients will suffer from this complication and which ones will not have the slightest sign of any disturbance. Will Dr Meigs tell us whether, in his experience, the voltage, filtration, and amount of the daily increments have any influence upon the occurrence of nausea and vomiting associated with x-ray treatments?

This paper clearly demonstrates that something must be done to prevent patients from seeking aid only in the advanced stages of the disease. It is difficult to diagnose lesions in the abdomen early, but with our modern methods of diagnosis it is not as hopeless as formerly. Education is one of the best methods of cancer control. Make the people acquainted with the symptoms of cancer—this will cause them to seek treatment early in the disease. Advocate the complete physical examination—do it whenever opportunity affords. It is a well-known fact that this is far from an absolute means of discovering intra-abdominal malignancies early but it may help, and reports are appearing which state that some types of malignancies are seen earlier, especially those that are easily accessible.

An effort should be made to combat far-advanced malignancy when diagnosed. All hope

should not be abandoned so far as these patients are concerned. The moribund patient should not be treated, but far-advanced disease should not preclude all treatment. On the contrary, the patient with advanced disease should be given the benefit of what science has to offer.

Dr Meigs (*Concluding Remarks*)—Dr Childs and Dr Kress have shown me that there will be a considerable amount of discussion about the propriety of my paper. I only wish to bring out a few points, and these I think are of great importance when advising roentgen treatment for inoperable cancer.

- 1 The cancer is inoperable, and therefore a cure cannot be expected.
- 2 Therefore, large doses of treatment to cure the patient are not wise.
- 3 Light treatment and careful observation are essential. If any response is elicited, treatment can be increased.
4. The roentgenologist should refuse to treat any patient whom he thinks should not be treated and should certainly refuse treatment unless the surgeon shows him where the tumor is.
- 5 The roentgenologist should view the pathologic slides of the tissues he is to treat to familiarize himself with the types of tumors that respond and those that do not respond.
- 6 Miracles rarely happen, and because one or two patients have been relieved does not mean that all patients should receive as much treatment as can be given.
- 7 To relieve pain and to check fluid are real reasons for x-ray treatment, but to cure inoperable disease is an entirely different thing.

THE DOCTOR, LIKE ELIZA, CROSSING THE ICE

For some years the medical profession has led a threatened, hectic existence, skating on ice which grows thinner with time, says Dr Lucy Stone Hertzog, in the *Journal of the American Institute of Homeopathy*. Doctors know better than those in any other profession that Eliza crossing the ice was not necessarily fiction, and that the spirit of Legree is roaming at large the world over. While the issues of foreign policy are in the ascendant at present, the domestic issues threatening all medicine do not constitute a subject wrung dry—by any means—and we cannot detach our professional affairs from the political and military problems of the times.

It is self-evident that when there is mobilization of fighting strength in the United States, the medical profession will go into service along with the military, so national matters are very much our business. Because of its importance to military service, the medical profession

stands first in the great danger of regimentation as a so-called emergency measure in national defense. The proposed plans for the federal control of medicine could easily find here a plausible excuse and a ready-made opportunity for those determined on the matter to place medicine beyond hope of return to the sound methods of private practice. We dare not overlook this issue in the midst of clashing war and insane strife of a shocked and reeling planet.

These moves against medicine can be accomplished unobtrusively while the nation and Congress are so absorbed in defense measures that vigilance is relaxed, but disaster cannot strike if we as a united profession marshal our forces to intensify our efforts in each community and state by guiding the medical care of the poor, and demand our rights to be heard as a leading profession in the determination of our future and that of the public.

While serving a year as an intern in a hospital is an important part of American medical training, only 17 per cent of the medical schools of

the country now require it before the M D degree is awarded, figures issued by the American Medical Association show.—*Science Service*

Case Reports

SULFAMETHYLTHIAZOLE IN THE TREATMENT OF SEVERE TYPE II BACTEREMIC PNEUMONIA

Report of a Case Treated with Recovery, Complicated by Peripheral Neuropathy

SAUL SOLOMON, M D , and MENNASCH KALKSTEIN, M D , New York City

THE advent of chemotherapy has revolutionized the treatment of pneumonia, and many patients have survived who would have succumbed with other methods of treatment. Sulfapyridine has proved to be of such value that either this drug or some substitute will henceforth be employed routinely in the management of pneumonia, although in selected cases drugs may be used in conjunction with specific antiserum.

Despite the excellent results which have been reported with sulfapyridine, the search for other effective drugs is unabated. This is because of the known toxic effects of sulfapyridine and also because certain strains of pneumococci, regardless of type, are resistant to this drug. Sulfamethylthiazole, one of the newest chemicals introduced, is, like sulfapyridine and sulfathiazole, a synthetic derivative of sulfanilamide. The following structural formulas of these compounds will indicate their relationship.

Sulfamethylthiazole is a white powder even more insoluble than sulfapyridine and is supplied in the form of half-gram tablets. This drug was first prepared by Fosbinder and Walter¹ in August, 1939, and has been demonstrated to be of value against the *Staphylococcus*, *pneumococcus*, and *Streptococcus hemolyticus*.^{2,3,4}

We have had the opportunity at Bellevue Hos-

pital from the Fourth Medical Division of Bellevue Hospital (Dr. Charles H. Nammack, director), and the Bellevue Hospital Pneumonia Investigation.

The sulfamethylthiazole was supplied to us by the Lederle Laboratories and the Winthrop Chemical Company.

pital to study the clinical effect of sulfamethylthiazole as part of a pneumonia investigation, and our complete data on this subject have not as yet been submitted for publication.* The case we report here is significant because it illustrates both the great merit of the drug and the only serious drawback to its more general use.

Case Report

T. H., white man, aged 52, became ill several weeks before admission with a chest cold characterized by cough, mild fever, and substernal soreness. One week before admission he had severe chills and raised a thick brown sputum, these latter symptoms coinciding with the onset of true pneumonia. He continued to work though he felt extremely weak and finally collapsed on April 9, 1940. He was then admitted (on the eighth day of illness) appearing critically ill, with dyspnea, cyanosis, and dehydration. His temperature was 39.4 C on admission and rose quickly to 40.8 C (Fig. 1). On physical examination there were signs of consolidation in the upper lobe of the right lung, and this was confirmed by x-ray (Fig. 2). The white cells numbered 13,150 with 74 per cent polymorphonuclears. The sputum was rusty, mucoid, typing by the direct method and by mouse inoculation yielded type II pneumococci.

A blood culture taken on admission showed many colonies of type II pneumococci, too many to permit an accurate count but estimated to be between two and three thousand per cubic centimeter of blood.

Sulfamethylthiazole was started shortly after admission, 2 Gm. being given at once and 1.5 Gm. every four hours. Because the level of the drug in the blood was not high (1.6 mg. per hundred cubic centimeters of blood), the more soluble sodium salt of the drug was substituted on the following day, 1.5 Gm. being given every four hours. The concentration of free sulfamethylthiazole rose to 8 mg. per hundred cubic centimeters and remained between 6 and 8 mg. for the next few days.

A favorable effect on the bacteremia was quickly noted, since in twenty-four hours there were only 2 colonies of type II pneumococci per cubic centimeter of blood and within forty-eight hours the blood became sterile and remained so throughout the duration of the illness.

The clinical response was almost equally striking as shown in Fig. 1. The sodium sulfamethylthiazole was continued for eight days to guard against the possibility of relapse. The patient received 8 Gm. of sulfamethylthiazole and

* Dr. William Kammerer was associated with us in this study.

FIG 1

72 Gm of sodium sulfamethylthiazole No immediate toxic effects were observed.

Following the crisis, the patient ran a low-grade fever for two weeks, although all signs of toxicity disappeared Agglutinins to the type II pneumococcus were never detected in his blood, though the slide agglutination test was done repeatedly during the period of observation. Furthermore, the Francis test on the twelfth and sixteenth days of illness was negative, despite the fact that the patient was obviously recovering. Because of the intense bacteremia complications such as empyema, endocarditis or meningitis was looked for but did not develop There was, however, delayed resolution, and several roentgenograms over a period of two months showed incomplete clearing of the pneumonia with slight deviation of the trachea to the right Bronchoscopic examination revealed no foreign body or any bronchial lesion The patient was afebrile and completely asymptomatic when he was discharged on June 15, approximately two months after admission

On July 5 he returned to the outpatient department of Bellevue Hospital complaining of pain and paresthesias in the extremities with difficulty in walking and maintaining his

equilibrium He was readmitted to the ward, and neurologic examination revealed definite evidence of peripheral neuropathy There was moderate weakness in the hands and marked weakness in the lower legs with particular involvement of the peroneal group of muscles There was a moderate degree of atrophy of the involved muscles All the reflexes were present except the ankle jerks There were no pathologic reflexes His gait was of the steppage type with a tendency to ataxia and swaying Sensation was normal except for faint and patchy hypalgesia in both feet and diminution of vibratory sense in both feet Spinal fluid was normal except for a slight increase in protein (50 mg per hundred cubic centimeters) The electrical reactions as determined by Dr F A. Quadfasel showed a partial reaction of degeneration in the abductor pollicis brevis of both hands and in the muscles of the lower legs and feet

Treatment consisted of large doses of vitamin B₁, the B complex, vitamin E, and physical therapy

After six weeks numbness and paresthesias had practically disappeared. There remained slight weakness in the gastrocnemius and moderate weakness in the peroneal and tibial group and in

FIG 2

FIG 3

the intrinsic muscles of the feet. Ankle jerks were still absent, and vibration sense was still impaired. There was a disappearance of atrophy of all the involved muscles. The gait was considerably improved and ataxia, steppage, and swaying were no longer present. The electrical reactions showed a marked recession of the reaction of degeneration with restoration of response to faradic stimulation.

It is our impression that improvement has been progressive and continuous, although it will require a long period of observation to determine whether or not there will be any permanent impairment of the peripheral nerves.

Serial x-rays demonstrated further clearing of the pneumonia, although the most recent picture taken on August 29 (Fig 3) still showed a patch of infiltration and fibrosis in the upper lobe of the right lung.

Comment

This report concerns a patient suffering from type II pneumonia with very severe bacteremia, who was treated with sulfamethylthiazole and recovered.

The mortality rate with even mild invasion of the blood stream by type II pneumococcus is extremely high. Bullowa⁵ reported that the mortality rate of untreated bacteremic type II pneumonias was 71.6 per cent. Furthermore, he observed that once the blood had been invaded with the type II pneumococcus serum therapy was of little avail. The mortality rate of the corresponding serum-treated group was 64.1 per cent. Cecil and Plummer⁶ reported that in a large series of untreated (control) type II pneumonias with bacteremia there were only 3 patients who had more than 5 colonies per cubic centimeter in the blood culture plates who re-

covered. One of these patients showed 68 organisms per cubic centimeter of blood, and his recovery was considered phenomenal. When the number of colonies per cubic centimeter of blood runs into thousands, as in this case, the outcome has been uniformly fatal by any previous methods of treatment. Hence, the favorable result here affords evidence of the potency of the chemotherapeutic agent used in this instance of bacteremic type II pneumonia. Our further experience (to be reported) leads us to believe that it is also effective against other types of pneumonia.

The appearance of widespread peripheral neuropathy during convalescence was attributed to a delayed toxic reaction to sulfamethylthiazole. The neuropathy improved greatly after several weeks. The incidence of this complication is estimated by the manufacturers to be less than 1 per cent. However, because of the possibility of this effect from the use of the drug, the manufacturers decided voluntarily to withdraw sulfamethylthiazole from clinical research.

RECURRENT PNEUMOCOCCIC INFECTIONS IN NEPHROSIS
TREATED WITH SULFAPYRIDINE

HERMAN SCHWARZ, M D , and SAMUEL B. WEINER, M D , New York City

WE ARE prompted to report this case of pneumococcic sepsis in a nephrotic child because of the results of treatment with sulfapyridine. The recurrent pneumococcic sepsis and the various purulent complications during this child's illness raised numerous problems of therapy. Many general clinical problems relating to the use of sulfapyridine were clarified in this case.

Case Report

H. K., a Jewish boy, aged 18 months, was first admitted to the Pediatric Service of the Beth Israel Hospital on January 28, 1939, complaining of swelling of the eyelids of four days' duration.

The family history was negative and irrelevant to the present illness. The child's birth was normal. He was formula fed, and solid foods were added to the diet at an early age. Orange juice was given daily, but no cod liver oil was offered. His development was normal, and the child was always somewhat large for his age. At 6 months he had pertussis of moderate severity and at 8 months he had varicella. No history of renal disease could be elicited. No previous urine examinations were made.

For one month prior to admission the child had not been entirely well. There had been persistent rhinorrhea but no elevation of temperature. Four days prior to admission edema of the eyelids was first noted. The child had urinated frequently for twenty-four hours prior to admission. There was no associated vomiting or convulsions and no other complaints.

Physical Examination—The examination revealed a white boy, well developed and well nourished. There was no dyspnea or cyanosis. Marked edema of the eyelids and marked pitting edema of the legs were present. The temperature was 101 F., pulse, 124, respirations, 30. The fundi of the eyes were negative. A mucopurulent nasal discharge was present, and the pharynx was injected. The tonsils were injected and hypertrophied, but both eardrums were normal. There was no cervical adenopathy or rigidity. The lungs were negative to auscultation and percussion. The heart was normal in size and shape, rhythm was regular, and no murmurs were heard. The abdomen was somewhat distended, and a suggestive fluid wave was present. No organ masses were palpated. The extremities, joints, and neurologic examination were negative.

Laboratory Examination—The Schick test was positive, the Pirquet and Mantoux test (1 mg.) was negative. Blood count revealed hemoglobin, 92 per cent (13 Gm.), red blood cells, 5,100,000, white blood cells, 11,200, polymorphonuclears, 76 per cent, and lymphocytes, 24 per cent. Throat cultures showed January 28, 1939—hemolytic streptococci and nonhemolytic *Staphylococcus aureus*, January 30, 1939—*Pneumococcus* type XXIV and hemolytic strep-

tococci. Urinalysis revealed 3 plus albumin, 3 to 4 hyaline casts, occasional white blood cells, no red blood cells, specific gravity 1020, sugar negative. The McClure-Aldrich test was five minutes. Urine culture showed few hemolytic streptococci, *Staph. aureus*—nonhemolytic, enterococcus. The blood sedimentation rate was 120 mm. in forty-five minutes (normal rate is 10 mm. in forty-five minutes). Daily blood pressures varied from 80 to 120 systolic and 50 to 80 diastolic. Blood chemistry revealed non-protein nitrogen, 38 mg. per hundred cubic centimeters, cholesterol, 454 mg. per hundred cubic centimeters, cholesterol esters, 288 mg. per hundred cubic centimeters, calcium, 10.3 mg. per hundred cubic centimeters, phosphorus, 3.5 mg. per hundred cubic centimeters, total protein, 3.98 per cent, albumin, 0.99 per cent, and globulin, 2.99 per cent. An x-ray of the chest was negative.

Course—Two days after admission there was a sudden chill and rise in temperature associated with an increase of abdominal ascites and abdominal tenderness. A blood culture at this time revealed 200 colonies of *Pneumococcus* type XXIV per cubic centimeter of blood. Abdominal puncture in the left lower quadrant yielded 2 cc. of a purulent fluid containing many polymorphonuclears and a few lancet-shaped diplococci, which on culture also proved to be *Pneumococcus* type XXIV. At this time sulfapyridine was begun (see Fig. 1). The drug was given by mouth except for a few days when because of persistent vomiting it had to be given by rectum. Within thirty-six hours the boy was less toxic, his temperature dropped to normal, and the blood culture was positive in one broth flask only. The abdomen soon became less tender. The blood culture ninety hours after therapy was begun proved to be sterile. With the subsidence of the peritoneal symptoms a small patch of consolidation and fluid was found in the lower lobe of the left lung. The throat culture, which had shown *Pneumococcus* type XXIV earlier, now showed no pneumococci. Temperature and pulse remained normal. X-ray confirmed the pneumonia of the lower lobe of the left lung and pleural effusion.

After two days of normal temperature, sulfapyridine was intentionally stopped. In twenty-four hours the child's general condition again became poor, the temperature rose, and the blood culture showed *Pneumococcus* type XXIV in one of the fluid mediums. Sulfapyridine was resumed with a prompt drop of temperature and sterilization of the blood within twenty-four hours.

During this time the boy's edema increased and became especially marked around the scrotum, which soon was enlarged to the size of a grapefruit. An erysipeloid eruption developed here. Skin culture (done by withdrawal of some fluid into sterile saline) was negative. In spite of a normal temperature, the boy's condition during this period was not good. Two trans-

FIG 1 Showing pertinent findings during first and second hospital admissions ——— Peritonitis ——— Pneumonia L L L ——— Erysipeloid reaction on scrotum ——— Erysipeloid reaction on abdomen ——— Otitis media ——— Pneumococcus skin abscesses—thigh ×××× Pneumonia R U L Rt Empyema

fusions and an intravenous injection of glucose 5 per cent in Ringer's solution had to be given. During the following week the erysipeloid eruption advanced slowly, but within a few days it subsided. During this time sulfapyridine was being given (see Fig 1).

In the third week the child's general condition began to improve. The blood culture and ascitic fluid proved to be sterile on examination, but the edema and ascites were markedly increased. However, tremendous diuresis suddenly developed without any special therapy and resulted in a rapid loss of weight. The sulfapyridine dosage was then diminished and stopped as the boy lost his edema.

At this time three large abscesses were first noted on the thighs. These were aspirated and *Pneumococcus* type XXIV was obtained. The blood culture repeated at this time was negative. The abscesses were incised and drained and healed rather slowly.

Following this severe infection with its sepsis, peritonitis, pneumonia, erysipelas, and multiple abscesses, the child's renal condition improved. The amount of urinary albumin diminished, the blood proteins rose, the appetite improved, and the child gained weight. On March 8 a scarlatiniform eruption was noted over the body and extremities. No cause could be found for this. We believed we were dealing with a drug

eruption due to sulfapyridine. The eruption disappeared when the drug was stopped. However, a few days later the drug was again begun, but no eruption developed subsequently. Whether this rash was a toxic manifestation or a drug rash could not definitely be decided. In view of the subsequent history and tolerance of the drug one would favor the former explanation.

On April 2 the boy was discharged from the hospital in good condition. No edema was present. There was very slight albuminuria. The blood proteins were high. The boy was instructed to continue on a high protein, low salt diet and to avoid respiratory infection.

He did well at home for only one week, and then he developed cough and fever associated with moderate dyspnea. For one week the boy was treated at home with sulfapyridine but failed to improve. He was then readmitted to the Beth Israel Hospital on April 25, 1939. At this time he presented no edema. He was acutely ill with marked dyspnea, some cyanosis, and a severe hacking cough. The pharynx was injected, and the ears were likewise full and injected. There was flatness and diminished breathing over the right base and in the right axilla. The heart was not shifted in position. The abdomen showed no ascites and no tenderness and there were no skin abscesses. The urine contained no albumin, red blood cells, or casts.

The blood culture on admission revealed many colonies of *Pneumococcus* type I. Chest aspiration yielded thick pus—growing *Pneumococcus* type I. X-ray of the chest showed a right sided effusion and a pneumonia of the upper lobe of the right lung.

Sulfapyridine was again given and was followed by a prompt drop in temperature and improvement in general condition. Within twenty-four hours the blood culture was negative, but the chest aspiration still revealed thick pus with a positive culture for *Pneumococcus* type I. Three chest aspirations yielded 20 to 40 cc of thick pus. This pus reaccumulated every two or three days, and after several aspirations thoracotomy was done on May 5, 1939. Although the first aspirations cultured *Pneumococcus* type I, the subsequent fluids were sterile. However, smears of the pus showed the organisms.

Although the first urines were found to be negative, massive albuminuria reappeared. However, there was no edema. Blood pressure was 100/80. Blood chemistry was normal with regard to proteins and cholesterol. Following the thoracotomy there was complete recovery in an uneventful manner. The child has remained well for one year. His last urine examination was negative.

Comment

Nephrosis is frequently associated with pneumococcal sepsis and purulent pneumococcal invasions of the lungs, peritoneum, pleura, and occasionally meninges. These complications occur frequently and often successively in this condition. Many nephrotic children suffer repeated attacks of sepsis with the same organism. The mortality of 50 per cent in some 40 cases of nephrosis we have collected has been due to sepsis—pneumococcal in almost every case.¹ Although the type of kidney pathology in the case we have presented cannot be definitely stated at the present time, it is most likely true lipid nephrosis.

The severe sepsis which this boy survived is rather unusual. We attribute this in part to sulfapyridine. The clinical picture and clinical course seemed to be definitely affected by the administration of the drug. The administration of the drug was followed by sterilization of the blood and sharp drop in temperature, along with general improvement in the toxemia of the child.

The skin abscesses that developed during the sepsis did not become apparent until the drug was discontinued and the edema had disappeared. The latent development of purulent foci has been encountered with sulfanilamide therapy, especially in cases of mastoiditis. The same phenomena seem to occur with sulfapyridine. Skin abscesses are a rare occurrence in cases of nephrosis. It may be that sulfapyridine was instrumental in the formation of these fixation abscesses.

It is more frequent for the same type of pneumococcus to cause the repeated episodes of sepsis

in any single child. In some cases the type varies in different episodes as it has in this case. Indeed we have seen infections with hemolytic streptococci follow pneumococcal infections.

Sulfapyridine seemed to be as effective for the type I pneumococcus sepsis as it was for the type XXIV sepsis. Although we do not know how early in the second attack of pneumonia sulfapyridine was begun and how high a blood level the child had while treated at home, we do know that empyema developed. The empyema fluid did not become sterile as soon as the blood did. Although large doses of sulfapyridine were used and frequent aspiration was resorted to, thoracotomy had to be performed. The bacteriologic examinations of the empyema fluid allowed us to demonstrate the bacteriostatic effect of sulfapyridine on the pneumococcus. Although the first two cultures were positive, the subsequent cultures were sterile in spite of the presence in the smear of the pus of organisms which gave a Neufeld reaction with type I pneumococcus antiserum.

With regard to the dosage and administration we were guided clinically by our experience with sulfanilamide, using 0.2 Gm. per kilogram per day as standard. We gave the drug orally in six-hour divided doses. The rectal doses were given in a specially prepared starch solution in eight-hour divided doses. Apparently a blood concentration of 3 to 5 mg per hundred cubic centimeters of sulfapyridine was sufficient to control the pneumococcus sepsis in this child.

The advantage of a drug such as sulfapyridine in the management of cases of nephrosis with pneumococcal infections is at once apparent. Even if antipneumococcus serum were as effective in the therapy of all types of pneumococcal infection, it could not easily be used in these cases of repeated infections without real danger of allergic phenomena. Indeed we feel that the prognosis in cases of lipid nephrosis should be much better since sulfapyridine seems to be a potent chemotherapeutic agent in the management of the intercurrent infections in these cases.*

* Since this case was submitted for publication we have had a child with chronic glomerulonephritis in the nephrotic phase in whom pneumococcus septicemia (type IV) developed along with metastatic peritonitis. In spite of prompt and vigorous treatment with sulfapyridine the child succumbed within thirty-six hours.

We also have knowledge of 2 additional cases of pneumococcus sepsis in children with nephrosis who succumbed in spite of prompt and vigorous therapy with sulfapyridine.

Therefore it would seem that the impressions from our first case were a bit too hopeful.

Therapeutics

CONFERENCES ON THERAPY

THESE are stenographic reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital, with collaboration of other departments and institutions. The questions and discussions involve participation by members of the staff of the college and hospital, students, and visitors. The next report will appear in the March 1 issue and will concern "Digitalis in Heart Failure."

Treatment of Pneumonia

DR HARRY GOLD The subject of the conference this morning is the treatment of pneumonia. We are fortunate in having Dr Conner here to open the discussion on the general management of the patient with pneumonia.

DR LEWIS A CONNER There is no aspect of medicine in which individual opinions differ more than in the details of treatment, the little details, which make up the general management. I think it might be well to review briefly what has happened in my own personal experience with respect to the methods of treating pneumonia.

Just before I became an intern at the New York Hospital, there was a period of several years when antipyretics seem to have been used as the chief remedy, the antipyretics such as antipyrine and antifebrin (acetanilid) having just come into use. They were used freely to reduce the temperature, of course, with distressing results.

When I was an intern at the hospital we relied upon alcohol almost exclusively as the remedy for pneumonia. It makes me shudder to think of the amounts of alcohol that were wasted and the number of patients' lives that probably were wasted in giving those enormous doses of alcohol, sometimes as much as a pint a day. Such amounts of alcohol must have increased greatly the tendency to peripheral circulatory failure.

Then, for a time, strychnine in large doses was the drug relied upon. Soon after that in the early years of this century there was an enormous enthusiasm for cold-air treatment. Every hospital had to rig up a roof in order to accommodate its pneumonia patients. The half-frozen nurses and half-frozen patients were kept on the roof all through the bitter winter nights, and some of them survived. Then there came a time when we felt that digitalis was perhaps the most important thing in the management of pneumonia. Then came the promising period when vaccines and

serums were used, and now we are in the latest period—that of chemotherapy.

I mention this series of remedies or methods of treatment because it seems to me that it ought to make us cautious about concluding hastily that we have got the answer now. We may have. Probably we have come much nearer to it than ever before, but it may be that in thirty, forty, or fifty years from now our successors will look back and think how gullible we were, just as we look back and think how gullible our predecessors were. There is no judgment that is more difficult to make than that of the effect of therapy. One has to take into consideration a great many things that we often fail to consider when we see some brilliant results or what we think are brilliant results. There are always many factors that cannot be estimated, and one needs to maintain an open mind and a severely critical judgment.

Now as to the management of pneumonia there is no type of patient needing hospital treatment more than the pneumonia patient. He needs a modern hospital bed that can be adjusted to his convenience and comfort. A cool room is essential, even though we do not put our patients on the roof now. We often manage to keep the room too warm, and most patients are much more comfortable when the room temperature is quite low.

It seems to me that we should strive for one thing especially and that is to make the patient as comfortable as possible. He cannot be entirely comfortable, but the saving of his strength, the saving him from pain, the protection of his sleep, and the avoidance of physical effort of various sorts are matters of a good deal of importance.

We ought to avoid the constant fussing around a patient. The nurse is so anxious to do everything that sometimes a pneumonia patient is continually occupied with something—medication, food, poultices, or stupes. He has very little actual rest unless it is care-

fully planned. It is best to group these various ministrations and to make a point of giving patients periods of two or three hours of undisturbed quiet without talking or moving or giving nourishment or medication.

Sleep is a problem. I have nothing to recommend particularly except that I think we should bear in mind when we are using these modern hypnotics that they all tend to disturb the respiratory center. That ought to be taken into consideration. If sleep can be produced by any form of physical therapy, that certainly is to be preferred.

Now as to the question of oxygen administration. I feel that I do not know as much about this as many of the younger men, but it seems to me that, particularly early in the course, the patient is often much more comfortable and is probably better for the use of oxygen. Moreover, I feel that it is desirable to combine it with some carbon dioxide for the stimulating effect upon the respiratory ventilation. There is some reason to believe that local atelectasis may play a part in the beginning of the pneumonic process and that fuller and deeper respiration may possibly lessen the chances of extension of that process.

The relief of pain is a very essential matter. Much of the restlessness, distress, fatigue, and exhaustion of the early days of pneumonia are due to the pain. There are, of course, many exceptions to that statement, but that is the general rule. It is a problem to know how best to relieve pain without giving so much in the way of drugs as to embarrass the respiratory center. Poultices and hot applications sometimes give a good deal of relief and sometimes none. Morphine or one of the opium derivatives is usually essential in the first days of the illness when the pain is apt to be most distressing. It is in the later stage that these drugs are more likely to be harmful, and then it is often possible to get along without them. Morphine, di-*laudid*, or *pantopon* should be used in small doses, frequently repeated. If large doses are given less frequently, one is apt to get into trouble, I think. One-eighth or $\frac{1}{4}$ gram of morphine sulfate given several times a day will often make the difference between a patient who is reasonably comfortable and one who is in great distress and is being exhausted physically and psychically by his pain.

As you know, pneumothorax has been suggested and used at the beginning of pneumonia in some cases. I have had no experience with it, but at least it seems to relieve pain completely when this is severe. I merely

raise the question whether, in a few cases in which the pain is so extremely severe that it dominates the whole clinical picture, artificial pneumothorax may not only be justified but actually desirable.

Then the question of circulatory failure. It is of the utmost importance for us to realize that in pneumonia we are dealing not with heart failure but with peripheral circulatory failure in almost every instance. That is still not as well understood as it ought to be. Whether the vasodilation is due to a central or to a peripheral action seems to be unsettled, but certainly it is not due to heart failure. Our problem then is the management of peripheral circulatory failure and collapse. It is easier to state the problem than it is to say how it can best be handled. Certainly, digitalis does not serve the purpose at all, and I feel about digitalis now very much as I felt about alcohol after we had got over the alcohol period, and as I felt about strychnine after the strychnine period was ended. Digitalis seems to be of value only in those infrequent cases in which the heart rhythm is disturbed and fibrillation has supervened.

For a number of years the use of digitalis in pneumonia was general, even though a good many of us, I think, were uncertain as to just what it accomplished. Then, in 1915, came the work of Cohn and Jameson, which showed for the first time that in acute infections and fevers such as pneumonia the electrocardiogram showed exactly the same digitalis effects as were seen in patients without infection or fever. That seemed to indicate that digitalis might have the same therapeutic effects as well and seemed to furnish a rational basis for its use in pneumonia. Then years later came the valuable statistical studies from Bellevue Hospital which showed convincingly that the patients treated without digitalis did rather better than those who received the drug.

As I have said, it is easier to recognize the existence of peripheral failure than to know how to deal with it. If such failure has followed prolonged and distressing pain, morphine is probably the most useful remedy. The drugs which, pharmacologically, would seem to be most suitable are ephedrine for its peripheral vasoconstrictor effects and caffeine for its effect upon the vasomotor center, but in actual practice it often is impossible to tell whether they are helpful or not.

Of the complications, severe abdominal distention is one of the most serious and refractory. If any tendency to such distention

exists, it should be combated rigorously by turpentine stupes, gentle laxatives, and the use of the rectal tube. My experience with pituitrin has not been very encouraging.

Pulmonary edema is seen usually as a terminal event for which little or nothing can be done, it is sometimes seen early in the disease, however, and then has a much less ominous significance. The administration of oxygen, the intravenous use of concentrated glucose solution, and dry cupping, all seem to be of value in combating it. Venesection in such emergencies has fallen into disrepute, but I am convinced that there are occasional instances in which it is fully justified.

DR GOLD. Dr Plummer will discuss the specific therapy of pneumonia.

DR NORMAN PLUMMER. In the case of serum and certain of the sulfonamide drugs, we have available two effective specific agents for the treatment of pneumonia. Serum has been accepted for many years because of its sound immunologic rationale and because of its definite effect on the clinical course and the mortality rate of certain types of pneumococcus. Sulfapyridine and more recently sulfathiazole have been accepted because of their unquestioned clinical value and, in addition, because of their wider scope of action and ease of administration.

Serum and these new chemicals have entirely different modes of action. The sulfonamide drugs seem to have but one action—that of inhibiting the growth of susceptible microorganisms. Serum, on the other hand, is of a more complex nature, furnishing the patient with a variety of antibodies such as the precipitins which neutralize the toxic carbohydrate substance, the opsonins which make the bacteria susceptible to phagocytosis, the agglutinins which cause a clumping of the organisms, and a number of other substances which help the body counteract the infection. It has been aptly stated that serum fortifies the pneumonia patient while sulfapyridine injures the pneumococcus. From this analysis it would seem that the combination of serum and chemotherapy is preferable to the use of either of the drugs alone. Whether this is true is one of the present problems of clinical investigation, and as yet we do not know the answer.

Our recommendation at the present time is that sulfapyridine or sulfathiazole should be given to all patients, except those rare exceptions having known sensitivity to similar drugs, as soon as the clinical diagnosis of pneumonia is made.

Serum treatment, in addition to chemotherapy, should follow promptly the type diagnosis in certain cases. We believe that patients with type III pneumococcus infection, the type still considered the most serious, might well receive the combined therapy. All patients with other types should have the benefit of serum also first, when two or more lobes of the lung are affected, that is, in the more extensive and more rapidly progressive infections, second, when there is a known bacteremia, third, in patients over 50 years of age, fourth, in the group that includes patients in pregnancy or in the first or second week of the puerperium, last, when the treatment is begun after the fourth day of the pneumonia. In these groups we want to use every weapon that we have available at the start of therapy.

When any patient receiving sulfapyridine or sulfathiazole alone fails to show a definite response within twenty-four hours, we believe that serum should also be administered.

The toxic reactions known to occur following sulfonamide therapy are as follows:

1 *Nausea and Vomiting*—Vomiting occurs in 50 to 60 per cent of the cases receiving sulfapyridine in the usual dosage. Nearly every patient has nausea. In some cases the patients cannot describe exactly what is wrong with them, but we can observe it. Nausea and vomiting are much less frequent and less severe following sulfathiazole.

2 *Irritation of the Urinary System*—This is due to the formation of crystals, concretions, or even calculi. Microscopic hematuria produced by this mechanical irritation occurs frequently, but there may also occur gross hematuria, anuria and renal colic, and there may be nitrogen and drug retention. This reaction may follow either sulfapyridine or sulfathiazole.

3 *The Destruction of the Red and White Blood Cells*—This may result in a severe acute anemia or a severe leukopenia or even agranulocytosis.

4 *Toxic Hepatitis*—We have had only 1 patient in our large series in whom we felt that toxic hepatitis and jaundice were definitely associated with sulfapyridine administration.

5 *Drug Rash and Drug Fever*—These two conditions usually are associated but each may occur separately. This reaction occurs more frequently after sulfathiazole than after sulfapyridine.

6 *Effect on the Central Nervous System*—Mild delirium quite often occurs but never

with any serious consequence. Convulsions have been described following overdosage of sulfapyridine.

No absolute contraindication to sulfapyridine or the related chemicals exists except a known sensitivity to the drug. Extensive kidney involvement represents a relative contraindication to its use. Also a marked leukopenia or anemia offers a relative contraindication to the administration of an agent known to affect the blood cells. Furthermore, vomiting has serious consequences in some cases, and in these there is again a relative contraindication to sulfapyridine. On the other hand, some of our most striking therapeutic results have appeared in patients showing a marked leukopenia or a deep jaundice at the time chemotherapy was instituted.

While there are few contraindications to starting sulfonamide therapy, there are definite indications for discontinuing it. If gross hematuria or other evidence of severe renal irritation occurs, if an abrupt drop in the red or white blood cells takes place, if a moderate or severe jaundice appears while sulfapyridine or sulfathiazole is being administered, the drug should be discontinued immediately. Also, if fever persists or a rash develops, it should be discontinued.

The dosage of sulfapyridine or sulfathiazole remains empiric. No definite correlation between the dosage or the blood level of the drug and the clinical response has been ascertained. Some of the most satisfactory recoveries have occurred with a small total dosage and with a low blood concentration. At Bellevue we are continuing to use the dosage recommended by Evans and Gaisford in their original article, that is, 2 Gm. as the initial dose, and then 1 Gm. every four hours. Sixteen grams is about the average total dosage in the uncomplicated cases. Some physicians have used a higher initial dose, even as high as 5 or 6 Gm. of sulfapyridine, and some have given a much larger total dosage. We have obtained the impression from comparing their reports with our own results that the incidence of toxic reactions is higher in the series treated with the larger dosage.

Sulfapyridine and sulfathiazole are usually administered by mouth. Attempts to give these drugs by rectum have failed because the absorption is either very small or entirely absent. Following a method suggested by Blake, the chemists at the Lederle Laboratories have been able to prepare for us a solution of 10 per cent sulfapyridine in 50 per cent glucose. This we have given intravenously,

orally, and rectally without any reactions other than would be expected from the given concentration of sulfapyridine in the blood. When given orally, blood levels similar to those obtained by giving plain sulfapyridine by the same route are procured, but the curve rises more slowly, reaching its peak in twenty-four hours instead of in twelve hours. In a number of patients treated with the solution of glucose-sulfapyridine by mouth, it is our impression that the same clinical responses occurred but with less nausea and vomiting. This confirms the belief that the drug is tolerated better when its level in the blood rises more slowly. When the glucose-sulfapyridine solution is given rectally and also intravenously, a satisfactory concentration of free sulfapyridine in the blood is not obtained. The reason for the difference in the blood levels of free sulfapyridine produced by these routes may be explained by the fact that glucose-sulfapyridine itself is inert but is probably broken up in the gastrointestinal tract before absorption occurs.

The sodium salt of sulfapyridine, which is much more soluble than sulfapyridine itself, may be given intravenously. We suggest that the sodium salt should be used first, when immediate action of the drug is imperative, second, when oral administration is not possible, for instance in certain postoperative and comatose cases, and third, when the absorption of sulfapyridine from the gastrointestinal tract is insufficient.

The general use of intravenous sodium sulfapyridine is to be discouraged for several reasons. It is a highly alkaline solution and severe local reactions and even a slough may occur if the drug seeps into the subcutaneous tissues. Furthermore, the toxic reactions seem to occur more frequently when the drug is given intravenously in this form. Several severe immediate reactions have occurred. One case about which I have first-hand information had a convulsion following the injection of the usual dose. Another objection is the difficulty of maintaining an adequate blood level of sulfapyridine, since intravenous injections tend to produce peak concentrations which fall off rapidly.

Sodium sulfapyridine may be administered orally and also rectally with satisfactory absorption. At first it was believed that there was danger of serious local irritation or possibly necrosis of the mucosa. However, clinical trial has proved that the drug can be administered in this way without local irritation and with satisfactory absorption.

Sulfathiazole has been found experimentally to give about the same results in pneumococcic infections as sulfapyridine. Sulfamethylthiazole, another drug recently introduced for clinical trial, experimentally has the advantage of a wider scope of action. Particularly, it is more effective than either sulfapyridine or sulfathiazole against the staphylococcus. Clinically, sulfamethylthiazole was found to be effective against staphylococcus as well as pneumococcic infections. Peripheral neuritis, however, occasionally followed its use, and because of this serious toxic reaction its further trial has been abandoned.

DR GOLD: I will now ask Dr. Travell to comment on the pharmacology of the agents that have been mentioned.

DR. JANET TRAVELL: The use of sulfapyridine and sulfathiazole in pneumonia has been so widely publicized that it would be inappropriate for me to attempt any systematic discussion of their pharmacology. However, I should like to call attention to two facts that have been demonstrated experimentally and that should have important practical applications.

In the first place, it has been shown that different strains of pneumococci, even of the same type, vary widely in their sensitivity to sulfapyridine. MacLeod has produced a "sulfapyridine-resistant" strain of *Pneumococcus* type I by exposing the organism to gradually increasing concentrations of sulfapyridine in the test tube and also by giving subcurative doses of the drug in mice infected with the pneumococcus. Sulfapyridine loses its curative effect in the pneumonias of mice produced by this drug-fast strain. The drug-fastness acquired by the pneumococcus seems to be relatively permanent. Other investigators have also produced sulfapyridine-resistant strains of the pneumococcus. In addition, Schmidt and his collaborators have recently shown that such pneumococci are equally resistant to sulfapyridine, sulfathiazole, and sulfamethylthiazole. Differences in the metabolism of drug-sensitive and drug-resistant strains are being studied and may throw light on the fundamental mechanism of the curative action of these agents in pneumococcic infections.

The possibility of producing drug-fastness of the pneumococcus in pneumonia patients should be considered in connection with the dosage and choice of the sulfonamide compounds. It has even been suggested that whenever possible the tolerance of the organism to sulfapyridine should be determined by

in vitro tests before therapy is instituted. In view of the experimental facts, it would appear that dosage should be intensive at the outset of treatment and continued sufficiently long to prevent relapses. As Schmidt has indicated, it is probably futile to employ another sulfonamide compound when the infection has become resistant to treatment with any member of the group. There is also the possibility that an entire epidemic of pneumonia might be caused by a sulfonamide-fast strain of the pneumococcus, but at the present time this is only a speculation.

The second fact I wish to mention pertains to the so-called "synergism" between sulfapyridine and antipneumococcus serum. It has been shown in *Pneumococcus* type III infections of mice that a dose of sulfapyridine and a dose of antipneumococcus serum, which when used alone affords no protection, when combined procures survival in a majority of the animals. It is possible that these results may be explained by simple summation of the effects of these two agents rather than by a synergism. In any case, the results afford an experimental basis for the combined use of antipneumococcus serum and sulfonamide compounds.

Next I shall make a few remarks about some of the more controversial aspects of the treatment of symptoms arising during the course of pneumonia.

Dr. Conner has said that digitalis therapy in pneumonia is useful only infrequently. That certainly seems to be the consensus, but in spite of the existing evidence the administration of digitalis in pneumonia is still a routine in some sections of the country. For instance, in an article from Alaska published during the past year on the effects of sulfapyridine, I find this statement: "Another interesting feature of this type of treatment (sulfapyridine) is the fact that digitalis was not used for any of the three patients, whereas as a routine we have been using it for all patients with pneumonia." About two and a half years ago an article appeared from Brooklyn on the use of digitalis in pneumonia in which the author states: "I do not believe that the last word has been said about the use of digitalis in pneumonia."

It seems that the routine use of digitalis in pneumonia is not yet dead, and for that reason it seems worthwhile to call to your attention again the evidence obtained in the Bellevue Hospital study of digitalis in lobar pneumonia, published in 1930. About 800 cases of lobar pneumonia were studied, alternate patients,

as admitted, receiving digitalis and the others receiving none. The mortality in the entire digitalis-treated group was 41.4 per cent and in the control group 33.7 per cent, a difference of nearly 8 per cent. The group of patients that received the largest doses of digitalis had the highest mortality. At the time this investigation was started, many of the house staff and attending physicians objected to the withholding of digitalis from pneumonia patients. Before the study was completed, the objection was just the reverse. Other clinical studies on the value of digitalis in pneumonia have employed various schemes of dosage, have often been poorly controlled, and in some instances conclusions have been based on very small numbers of patients. None of these has yielded any convincing proof that as a routine procedure digitalis administration is of any value in either preventing or overcoming circulatory failure in pneumonia. Indeed, the routine use of full therapeutic doses may be dangerous. It should be emphasized, however, that digitalis should not be withheld from those patients showing unmistakable signs of heart failure or in those patients having auricular fibrillation with a rapid ventricular rate.

Dr. Conner used the expression "after we got over the strychnine period," but it seems that strychnine is another drug that from time to time enjoys a revival as a circulatory stimulant. As recently as 1937 an eminent clinician from Boston writes: "We have found strychnine in doses of from 2 to 4 mg ($\frac{1}{30}$ to $\frac{1}{15}$ grain), given at hourly or two-hour intervals, an effective remedy in acute circulatory collapse in infectious diseases, and particularly in pneumonia." Such statements appear in spite of the fact that there is not any good experimental evidence, either in man or in animals, that strychnine produces any such effects in doses smaller than those which induce marked hyperexcitability and convulsions.

This matter of strychnine seemed to have been settled by the results of several extensive investigations twenty-five to forty years ago. For example, Parkinson and Rowlands in 1913 carefully measured the effects of a single subcutaneous dose of $\frac{1}{16}$ grain of strychnine in 50 patients with congestive heart failure, and Newburgh studied the effect of repeated doses of $\frac{1}{10}$ grain each, in a similar group of patients. One patient received $\frac{1}{10}$ grain every two hours, making a total of 0.7 grain on the first, 0.7 on the second, and 0.6 on the third day, at the end of each of these days it

is said that "the patient twitched every time he was touched." Although strychnine was given in many times the usual therapeutic dose, none of the patients were objectively benefited, and no consistent changes in pulse rate, respiratory rate, blood pressure, or edema were observed. Newburgh, using $\frac{1}{10}$ grain doses of strychnine, also confirmed the early observations of Cabot made in 1904 in typhoid fever and pneumonia which showed that strychnine failed to produce any uniform rise in blood pressure in the circulatory disturbance of febrile states. At the present time there seems to be no justification for the use of strychnine as a circulatory stimulant in heart failure or in the acute infectious diseases.

A substance, possibly important in the circulatory failure of pneumonia, which has not been mentioned, is sodium chloride. Inadequate salt intake at a time of blood sodium depletion may result in dehydration of the blood and diminished blood volume and might conceivably be a precipitating factor in the production of circulatory failure. There are suggestions in the literature that the addition of moderate amounts of salt to the diet of the pneumonia patient may prove beneficial. On the other hand, the administration of large amounts of salt, of the order of 30 Gm daily, has been reported as sometimes resulting in the visible accumulation of edema fluid.

The barbiturates seem to be the most popular sedative and hypnotic agents in most conditions, not excluding pneumonia. If small doses of the barbiturates accomplish sedation, their use would seem to be entirely warranted. If these fail, however, the temptation is to give larger amounts, but the administration of larger doses may only increase the restlessness and excitement of the patient. The stimulant effects of the barbiturates are well known, being frequently observed after large doses in animals. Large doses of the barbiturates, as Dr. Conner has mentioned, may also directly depress the respiratory center.

The beneficial action of the barbiturates is usually attributed to indirect effects resulting from the quieting of the patient and the consequent reduction in metabolism. There is another possibility. Experimentally it has been shown that the barbiturates afford marked protection of the respiratory center against depression or paralysis by strychnine, presumably owing to the prevention of fatigue of the center by excessive stimulation. We have shown that within certain limits ethyl

alcohol also is antagonistic to the depressant action of strychnine on respiration. There is, thus, a basis for speculation as to whether in pneumonia suitable doses of these substances may not, under certain circumstances, bring about respiratory improvement not only by indirect effects but also by a direct protective action on the respiratory center. This would serve to raise the threshold of the center to stimulation, with consequent slowing of the already excessively rapid respiratory rate and greater pulmonary exchange.

DR CLARA GROSS I should like to ask Dr Plummer what the optimum dose of sulfapyridine or sulfathiazole for a child of 2 years is? Various figures are given, some quite high and some the opposite.

DR PLUMMER Children should receive about the same dosage of sulfapyridine or sulfathiazole as adults in proportion to body weight. It is true that there has been a difference of opinion, and some pediatricians use a considerably higher dosage than others. Dr Smith, at Bellevue Hospital, reported a large series of cases and states that the smaller dosage can be used just as effectively. I believe he has cut the total daily dose of sulfapyridine from 1 grain per pound of body weight to $\frac{3}{4}$ grain.

DR EDGAR MAYER If after a few days you discontinue the use of sulfapyridine because of blood destruction and then the blood is restored with transfusions, would you resume therapy with sulfapyridine, and what dosage would you use?

DR PLUMMER We believe that you would get severe reactions again and that it is unsafe as a rule to resume the drug. Two cases of severe hematuria have been reported in which there was a recurrence of severe hematuria when some months later the patients again received sulfapyridine. Judging from experience with similar drugs, when a severe reaction occurs, it is dangerous to use the drug again.

DR CONNER In the cases just mentioned, I suppose the hematuria was the result of local irritation from calculi.

DR PLUMMER Yes, it is our impression that the hematuria has been caused by local irritation from the calculi, concretions, or crystals of sulfapyridine.

DR CONNER There is never a general tendency to bleed?

DR PLUMMER No, we have not seen such a case.

DR GOLD I believe Dr Plummer said that occasionally the toxic effects involve the

destruction of the red cells and the white cells. Is the effect a destruction of the white cells or injury of the bone marrow?

DR PLUMMER I believe that it is primarily an effect on the bone marrow.

DR TRAVELL I should like to ask Dr Plummer if he makes determinations of the urobilinogen excreted in the urine. It has been claimed that that serves as an index to the amount of red blood cell destruction going on in the body. A series of 20 cases was reported in which 8 showed increased excretion of urobilinogen and 3 of those subsequently developed acute hemolytic anemia. Is that a reliable test?

DR PLUMMER We have not made such determinations in any of our cases. I think one criticism of the test is that some increase in the urobilinogen occurs in pneumonia itself. I think that was not fully taken into consideration in that report.

DR GEORGE A SCHUMACHER Dr Plummer, I would like to ask your opinion regarding this problem which comes up frequently in the pneumonia ward. Sometimes it takes a little time after admission to type these patients, or the pneumococci present in the sputum do not type out specifically. Would you go ahead and treat with sulfapyridine regardless of that fact and take the chance that later, owing to changes in the pneumococcus or at least in its capsule, you may not be able to find out what the type was? Furthermore, would you proceed to give sulfapyridine without knowing that the pneumococcus is the etiologic agent, provided you are confronted with lobar pneumonia?

DR PLUMMER Sulfapyridine is such an effective agent that it should be used without delay just as soon as the clinical diagnosis of pneumonia is made, and we should not wait for the results of typing or the results of blood culture. As far as I know, there is no good evidence that sulfapyridine has any effect on the capsule or on the typing of the pneumococci. That was reported at first, but that work has not been confirmed. With recovery of the patient after sulfapyridine therapy, the number of pneumococci in the sputum diminishes, making typing, particularly by the direct method, more difficult. However, the pneumococci that remain are not altered in any way. Furthermore, pneumococci present in pleural or spinal fluids with high sulfapyridine levels can be typed by the Neufeldt method.

DR EPHRAIM SHORR In your discussion of serum therapy you did not differentiate be-

tween horse and rabbit serum. I wonder if you would say something about that?

DR. PLUMMER One of the recent developments in the treatment of pneumonia has been the use of rabbit serum. At the present time we are using almost exclusively refined and concentrated rabbit serum. Rabbit serum is preferable because for most of the types it is possible to produce a more concentrated preparation. Also, it is possible to make a potent rabbit serum against all of the pneumococcic types, even type III. Recent reports of cases treated with rabbit serum show fatality rates comparable to those obtained when sulfapyridine is used.

DR. EUGENE F. DuBOIS What do you do in addition to keeping the patient busy with the dosage of sulfapyridine and with serum, the necessary blood counts, and so on? What other measures do you use in the way of drugs?

DR. PLUMMER We find that we have to use much less in the way of drugs than we did formerly. We use oxygen much less frequently than we did. We use the various measures that Dr. Conner has outlined for pain and occasionally for stimulation of the circulation. It seems to me that we really employ much less nonspecific therapy now than we did formerly.

DR. TRAVELL Is it customary or advisable to give sodium bicarbonate together with sulfapyridine as is usually done in the case of sulfanilamide?

DR. PLUMMER Sodium bicarbonate is frequently used with sulfapyridine, although its value is questionable because we know that renal irritation may occur and sulfapyridine calculi may form even when the urine is alkaline.

DR. CONNER Is the pain usually influenced early in the treatment with sulfapyridine?

DR. PLUMMER I believe that it is. As you spoke about pain in your discussion it impressed me that the course of pneumonia had been considerably altered. It seems to me a long time since we have seen those uncomfortable patients for protracted periods. When we do see them and give them sulfapyridine, I must say that they are usually more occupied by thoughts of their stomach and of their digestion than they are of the pain in their chest.

DR. GOLD We should have a statement about the use of the epinephrine series in the treatment of pulmonary edema in pneumonia. Dr. Eggleston, have you anything to offer on this point?

DR. CARY EGGLESTON I am not enthusiastic about the use of epinephrine in pulmonary edema. I have not, in a number of years past, used epinephrine or any of its derivatives. I do not believe I have ever found it necessary. I think other agents such as morphine in adequate doses, phlebotomy when there is increased venous pressure, and the administration of oxygen suffice. These are much more satisfactory and less risky to the patient than doses of epinephrine or any of its congeners. So my experience with epinephrine in the treatment of pulmonary edema in recent years is nil.

DR. PLUMMER Should we ask Dr. Eggleston if epinephrine is contraindicated in the treatment of severe pneumonia?

DR. EGGLESTON Harking back to Dr. Conner's discussion of peripheral circulatory or vasomotor failure, theoretically it is contraindicated in that condition. Certainly I think experience shows that it is of relatively little use in combating the toxic forms of circulatory failure, and, since some disastrous results have been reported which seem justly attributable to the use of epinephrine, I would personally advise against it. I do not use it.

DR. GOLD How often do patients with pulmonary edema in the course of pneumonia recover?

DR. EGGLESTON You will have to ask the pneumonia people that. They are dealing in statistics.

DR. CONNER I think they do sometimes recover but not usually. Patients with an extensive fulminating onset, particularly in the first two or three days, may have a severe pulmonary edema and get over it, and then run along the normal course. Don't you think so, Dr. Plummer?

DR. PLUMMER I think that is true, and since we have been using sulfapyridine and sulfathiazole we have seen most remarkable recoveries. Some of the most striking responses that we have seen are in those individuals who came into the hospital with circulatory collapse, they may respond quickly to these agents and make most remarkable recoveries. I know it used to be said by many clinicians that they had never seen a pneumonia patient with pulmonary edema recover. I would have differed with that, but I think those people would now change their opinion.

DR. EGGLESTON The important point that deserves emphasis, it seems to me from my relatively limited experience with pneumonia is that the entire clinical picture of the course

of the disease has been changed radically for the better with the introduction of these more potent serums and more particularly with the introduction of sulfapyridine. Certainly, our wards are not filled with the desperately ill pneumonia patients as they used to be.

DR WILSON G SMILLIE Dr Plummer spoke of the ease of administration of sulfapyridine. When sulfapyridine first appeared, physicians breathed a sigh of relief from the administration of serum in private practice, but, as Dr Plummer has described it, the administration of sulfapyridine requires just as close or more close clinical application than does the administration of serum. It is perhaps more difficult to treat the patient in the home with sulfapyridine than with serum itself. Is that so?

DR PLUMMER Yes, I would say that these patients have to be watched very closely and that the pneumonia patient still belongs in the hospital rather than in the home. If you compute the cost of blood counts, urine analyses, and additional laboratory work that has to be done in the sulfapyridine-treated case at the present time, you will find that it costs just as much and there is probably just as great an expenditure of energy in taking care of patients treated with sulfapyridine as with serum.

DR GOLD Dr Travell, would you summarize today's discussion?

DR TRAVELL We have had a bird's-eye view of the therapeutic procedures that have had a vogue in the treatment of this disease during the past half a century, and the moral of this review is a caution against too great optimism in evaluating new remedies. An illustration of this point is the fact that the weight of pharmacologic evidence has disproved the original clinical impression that certain drugs, such as digitalis and strychnine, are of value in treating the blood pressure collapse in pneumonia.

In the management of pneumonia the details of treatment are important, especially those details that insure rest and comfort for the patient. The relief of pain should be secured by whatever measures are necessary, including the judicious use of morphine, poultices, physical therapy, or even artificial pneumothorax.

Sulfonamide therapy has produced such a change in the whole clinical picture of pneumonia that the relief of the pneumonic symptoms, pain, dyspnea, cough, and cyanosis, now rarely presents serious difficulties. Attention is focused rather on the problems arising from the toxic actions of the drugs, such as nausea and vomiting, hematuria, hepatitis, anemia or leukopenia, and drug fever. The clinical advantages of combining antipneumococcus serum and sulfonamide therapy is still a controversial matter, although evidence exists for the belief that combined therapy may be more effective than either serum or a sulfonamide compound alone.

The present status of our knowledge regarding important aspects of sulfonamide therapy has been concisely presented its mechanism of action, the indications for combining serum therapy with it, the contraindications to its use, plans of dosage, the effective routes of administration of sulfapyridine and its soluble sodium salt and some allied compounds. It has been hinted that opinions on these points should not be too fixed and may be modified as time passes. For instance, a total dose of 16 Gm of sulfapyridine seems to be all that is necessary in the average uncomplicated case of pneumonia, but the criteria for dosage are not yet clearly defined, and it is possible that smaller doses may prove equally effective. In children, cutting the total daily dose from 1 gram to $\frac{3}{4}$ gram per pound of body weight seems not to have reduced the efficacy of sulfapyridine therapy.

MAINTAINING THE SUPPLY

The decision to exempt medical students from conscription till after completion of their internships assures the nation of a continuous supply of qualified physicians, says the *New York Medical Week*. This is a prime necessity in war or peace. The country would lose more than it stands to gain by interrupting the arduous tempo of the medical course for military training.

It goes without saying that the medical student has as great an obligation as anyone else to share in the defense of his country. The career for which he is fitting himself, however, is an essential part of any preparedness program. He

can render greater service during his period of conscription if he is already equipped with the professional skill he will exercise later on than if he is drafted during his student days, when he is neither physician nor soldier.

For the young men in medical school, therefore, there is no greater patriotic duty than to complete their studies promptly and well. They are being granted deferment because the government believes they can serve the country better after graduation than before. In return for the privilege of completing their professional studies without interruption, they are expected to spare no effort in those studies.

Medical News

Southern Medical Association's New President

THE *Southern Medical Journal* in its January, 1941, issue carried the following editorial on Dr Paul Henry Ringer, of Asheville

"A man of many gifts is the new president, Dr Paul H. Ringer, a linguist and a musician, as well as one of the most scholarly members of the medical profession.

"He was born in New York City, November 6, 1881, the only child of Severn and Elisa Minot Ringer. His father, a Pole by birth, was Professor of Modern Languages at Lehigh University. His mother was a Belgian, and an accomplished musician. Dr Ringer attended private schools in New York, received his A B from Columbia University in 1901, and his M D in 1904. He served internships in Bethlehem, Pennsylvania, and New York City, and came to Asheville, North Carolina, to begin practice in 1906. He was associated with the late Dr Charles L. Nimor, and specialized early in diseases of the chest. His years of practice have covered the period of prominence of Asheville in the field of tuberculosis, and he himself has achieved prominence for his work particularly in this disease.

"In 1915 Dr Ringer married Miss Eleanor Varick Morrison, of Asheville. They have two children, Paul, Jr., a graduate of Princeton and now a student at the Vanderbilt University Medical School, and Eleanor, who is at Sweet Briar College.

"In the World War Dr Ringer served as Captain in the Medical Corps of the United States, attached to the Italian Army at Base Hospital 102 in Vicenza, Italy. He has had many medi-

cal and civil honors, including the presidency of his state medical association and of leading organizations for the study and prevention of tuberculosis.

"He speaks French and German fluently, has a singing voice of fine quality, and is a gifted speaker. A fluent writer, he is also an omnivorous reader with a catholic taste in literature. He has made many contributions to medical periodicals. He is broadly civic minded and in Asheville has headed the Community Chest among other charitable organizations, and the Civic Music Association, and he is active in the Presbyterian Church, in which he is an elder. His memberships include the Columbia University Club of New York, Biltmore Forest Country Club, Pen and Plate Club, and the Civitan Club.

"He has been president of the Southern Tuberculosis Conference, has held office in several of the special societies, and is a diplomate of the American Board of Internal Medicine.

"In 1913 he joined the Southern Medical Association and since then has attended twenty of its meetings. In 1928 he was General Chairman of the Asheville meeting of the Southern Medical Association and for six years represented North Carolina on the Council of the Association.

"To a rare degree he combines the qualities of scholarship, ability as an internist and diagnostician, leadership and forceful speaking. Few men have reached the presidency of the Southern Medical Association so well equipped for the office and with such widespread approval of his associates as has Dr Ringer."

Progress of the War on Infantile Paralysis

SEVERAL important developments were reported at the first annual medical meeting of the National Foundation for Infantile Paralysis at the Waldorf-Astoria Hotel in New York City on November 7 and 8.

Grantees receiving funds are making studies in epidemiology, virus research, relationship of nutrition to poliomyelitis, and the prevention and treatment of the disease. In addition, a program of professional and lay education has been promoted.

Some of the problems are so baffling that the workers can only report progress or tell of promising leads being followed up, but in other cases the news is more encouraging.

Research on the Virus

The Committee on Virus Research reported that studies were being conducted to determine the nature of the poliomyelitis virus. Paul F. Clark, Ph D, of the University of Wisconsin, has concentrated the virus infected material obtained from spinal cords of monkeys so that infection may be produced in dilution of one part to ten million. Dr Hubert S. Loring, Leland Stanford University, who has been studying the purified and concentrated virus,

concluded that the virus is protein in nature, or contains protein material. The properties and chemical nature of the virus will continue to be studied.

Drs John R. Paul and James D. Trask, Yale University School of Medicine, reported the finding of the poliomyelitis virus in stools of patients, contacts, and in sewage collected from epidemic areas. Dr S. D. Kramer, Michigan Department of Health Laboratories, reported the occurrence of healthy carriers in an institutional outbreak in Detroit.

Reports were made of the efforts to produce infection with poliomyelitis viruses in animals other than the monkey. This confirmed the previously reported findings of Armstrong to the effect that the Lansing strain could be made to produce infection in various cotton rats. All investigators, excepting Dr John A. Toomey of the Western Reserve University School of Medicine, reported that only this one strain could be made to produce disease in the cotton rat. Toomey, however, had success in growing, by a special technic, several other old as well as newly isolated strains in the cotton rat. This observation may be of utmost importance in conducting further clinical and epidemiologic studies.

The distribution of the virus in the body was reported by Drs R D Lillie, the National Institute of Health in Washington, Albert B Sabin, University of Cincinnati, John F Kessel, University of Southern California, and others. All showed that the virus could be routinely recovered from central nervous tissue of human fatal cases and from experimental animals, and that excepting for tonsils, adenoids, and lymph gland tissue, no other part of the body was shown to harbor the infection.

Studies of Immunity

Studies on the development of active and passive immunities were reported. All attempts at producing immunity have thus far met with failure. Dr Kessel reported that one infection did not routinely protect monkeys from subsequent disease on re-inoculation. He also made the observation that there was little relationship between the presence of neutralizing antibodies in the blood stream and immunity to the disease.

Investigations of Aftereffects

Reports were received from grantees who are studying both the effects of the disease and the methods of prevention of damage. Dr Donald Young Solandt, University of Toronto, concluded that the muscular fibrillation resulting from nerve destruction is not the primary cause of atrophy of paralyzed muscle. Dr Clinton N Woolsey, Johns Hopkins University School of Medicine, concurred in these results, but Dr Samuel Soskin, Michael Reese Hospital in Chicago, felt that in the animals which he studied fibrillation did play an important part in the degree of atrophy resulting from nerve destruction.

Gross and microscopic pathologic studies of paralyzed muscles carried on by Dr Herbert E Hips, the Crippled Children Hospital in Marlin, Texas, showed that occasionally muscles developed a bandlike form of degeneration, and that when mattress sutures were used to connect the muscle above and below these bands, good functional results were obtained.

Surgical Treatment

Several studies have been completed and others are still being conducted that measure the end

results of various forms of surgical and conservative treatment. Drs George E. Bennett and Raymond E Lenhard, The Children's Hospital School in Baltimore, concluded that if the maximum benefits of physical therapy are to be secured, patients must be under such care within six months of the onset. They further showed that 97 per cent of all weakened or paralyzed muscles regain the maximum possible strength within eighteen months after onset of treatment. Dr William B Carrell, Texas Scottish Rite Hospital in Dallas, confirmed these observations. In addition, he concluded that rest with physical therapy in the hospital had no advantage over similar treatments given in the home. Hospital care over long periods was of decided advantage only when underwater treatments were used. Dr Carrell also pointed out the disadvantages of plaster casts continued over periods of from four to six months, even when the patients reported for frequent reapplications of the casts.

The value of rest treatment was further emphasized by laboratory studies on infected monkeys. Dr Sidney O Levinson, Michael Reese Hospital in Chicago, showed that monkeys forced to exercise during the active disease process had not only a greater amount of paralysis but also a higher death rate.

Educational Activities

To inform both professional workers and the public of certain aspects of this disease an educational program has been conducted. An exhibit at the New York World's Fair was viewed by over five million persons. Scholarships have been made available through the National Research Council to physicians wishing to specialize in orthopedic surgery or virology. Other scholarships have been made available to nurses wishing to specialize in the orthopedic aspects of public health nursing. Graduate instruction in physical therapy also has been provided.

Booklets have been prepared and widely distributed dealing with the use of the respirator, the nursing care of poliomyelitis patients, and other phases of the problem.

At this meeting additional grants were recommended for continuation of existing studies or new investigations in the amount of \$137,350.

County News

Bronx County

The Speakers Bureau of the county society has compiled a list of medical topics on which its members will deliver free talks before local organizations.

Bronx pharmacists have adopted the practice of delivering prescriptions containing narcotics either to the patient's home or to the prescribing physician's office to thwart users of fake prescription blanks, it was revealed at a recent meeting of the public relations committee of the Bronx County Medical Society.

A resolution was adopted deeming it "poor taste" for prescription blanks to be printed by pharmacists bearing the latter's name. Methods were discussed to amend or revoke the law permitting podiatrists to use the title "doctor" with their names in 1943. It was suggested

that the State Society select an outstanding physician as a candidate for the legislature.

Dr Joseph Golomb, president of the county society, was one of the principal speakers at the dedication of the new \$400,000 Tremont Health Center on January 7.

The county society met at Burnside Manor on January 15 and listened to the following program.

"Allergy in General Practice" by Dr Aaron Brown, "Allergic Dermatitis" by Dr Marion B Sulzberger, Discussion by Dr Abner Stern, Dr David Engelsher, and Dr Samuel Feldman. An elaborate and valuable dermatologic exhibit was also shown.

The number of maternal deaths in the borough of the Bronx in 1940 was less than in previous years by almost 42 per cent.

R

Wyeth's BEWON ELIXIR

A Vehicle that Stimulates the Appetite

Wyeth's BEWON ELIXIR is an excellent vehicle for many medicaments. It is compatible with most drugs.

Standardized to contain 500 International Units of Vitamin B₁ (thiamin chloride) per ounce, BEWON ELIXIR stimulates the appetite and is indicated in Vitamin B₁ deficiencies.

JOHN WYETH & BROTHER
INCORPORATED • PHILADELPHIA, PA.

Broome County

The members of the county society were guests of the officers of the Thirty-first Medical Regiment at the meeting on January 14 at the Binghamton City Hospital. Lieut-Col R J Wharton, Medical-Reserve Commanding Officer of the 31st Medical Regiment spoke on "The Medical Regiment," illustrated by a sound motion picture. Major Fred L Ritter, Medical-Reserve, Assistant Plans and Training Officer for the 1st Military Area at Syracuse, discussed "The Army Medical Service and the Civilian Physician." Open discussion and questions from the floor followed.

Radio talks were given on the five Thursday evenings in January by Drs F M Dyer, Jacob Zillhardt, C B Henry, R. J McMahon, and Vesta M Rogers.

Cayuga County

Dr Wilfred Sefton was elected president of the county society at the 135th annual meeting which preceded a dinner in the Palm Room of the Osborne Hotel in Auburn on December 19.

Other officers elected were vice-president, Dr M O Parker, secretary, Dr S J Karpenski, treasurer, Dr Robert J Thomas.

Dr Harry S Bull was elected delegate to the convention of the State Society and Dr George C Sincerbeaux, alternate. Dr Donald M Green was elected to represent the county society at the convention of the Seventh District with Dr W B Wilson alternate.

The censors chosen consist of Dr W A Tucker, Dr D D Althouse, Dr W B Wilson, Dr L D Burlington, and Dr E H Wood.

Chemung County

Dr Charles Hendee Smith, of New York University College of Medicine, arranged a course on pediatrics for the Chemung County Medical Society. The first lecture, titled "The Pneumonias of Childhood," was presented by Dr Smith on January 8. Other lectures in the series will be given as follows at the Mark Twain Hotel, Elmira: 6 30 p.m. February 12, "Rheumatic Fever, Chorea and Heart Disease," Dr Katherine Dodge, professor of pediatrics, New York University College of Medicine, March 12, "Preventive Pediatrics and the Periodic Health Examination," by Dr Gaylord W Graves, clinical professor of pediatrics, New York University College of Medicine.

Plans for a fourth lecture on "The Growing Feet of Children" are being made.

Cortland County

At the annual meeting of the county society on December 20, the following officers were elected for 1941: president, Dr Robert H Brink, vice-president, Dr Harvey S Kinne, treasurer, Dr Bert R. Parsons, secretary, Dr William A. Wall, delegate, Dr James Walsh, alternate, Dr Daniel R. Reilly, all of Cortland.

—Reported by W A Wall, M.D., Secretary

Delaware County

These officers for 1941 were elected on December 21 at the annual meeting of the county society at the Elm Tree Restaurant in Delhi:

president, Dr Jerome Kogan, Stamford, vice-president, Dr Floyd R. Bates, Walton, secretary, treasurer, Dr Orrin Q. Flint, Delhi, delegate to state convention, Dr Robert Brittain, Downs-ville.

Dutchess County

The county society held its annual meeting on January 8 at the Hudson River State Hospital. A talk was given on "Diagnosis and Treatment of Arthritis," by Dr Currier McEwen, head of the arthritis clinic at New York University College of Medicine.

The following officers were elected for the ensuing year: president, Dr James T Harrington, Poughkeepsie, vice-president, Dr Edgar F Powell, Fishkill, secretary-treasurer, Dr John F Rogers, Poughkeepsie, secretary, Dr Louis W Stoller, Red Hook, censors, Drs Alva L Peckham, Howard P Carpenter, Gilbert S Tabor, Howard S Bulkeley, Julius E Haight, delegates, Drs Samuel E Appel and Scott Lord Smith, alternate delegates, Drs Earle W Voorhees and James J Toomey.

Erle County

The medical school of the University of Buffalo is giving a series of free public lectures in January and February on new developments in medical science.

The first lecture was given by Dr Earl D Osborne, professor of dermatology and syphilology, on "What You Should Know About Syphilis," on January 12.

Other speakers are:

January 26, Dr James E King, F.A.C.S., emeritus professor of gynecology, "Common Diseases of Women", February 9, Dr Herbert A Smith, professor of surgery, "Acute Appendicitis", and February 23, Dr David K Miller, professor of medicine, "Foods and Vitamins."

The series is sponsored by the medical school's newly established department of postgraduate and continuation teaching, of which Dr A. H. Aaron is chairman.

The department will conduct the annual two-week postgraduate course for physicians, will bring outstanding medical figures to Buffalo for lectures, will extend medical education to physicians of other counties of Western New York and will disseminate knowledge of latest medical advancement to the public.

The meeting of the section of obstetrics and gynecology of the Buffalo Academy of Medicine on December 18 was devoted to a symposium on "Care of the Newborn." On January 15, the Section of Medicine heard a paper on "Common Errors in Cardiac Diagnosis," by Dr A. C. Ernstone, of the Cleveland Clinic, and on January 22 the Section of Obstetrics and Gynecology listened to an address on "Endocrine Therapy in Gynecology," by Dr R. W. TeLande, of Johns Hopkins Hospital.

The inaugural meeting of the Western New York Surgical Association was held in Buffalo, at the General Hospital on November 26.

The morning Operative Clinics were conducted by the following physicians: Dr James E King, Dr Herbert A. Smith, Dr W W Plummer, Dr D C McKenney, Dr Walter L. Machemer, Dr James C Sullivan, Dr J Sutton Regan.

Jefferson County

The regular monthly meeting of the county society was held on January 9 at the Black River Valley Club Dinner was served at 6 30 "Fever Therapy" was discussed by Dr Nathaniel Jones, resident radiologist at the Strong Memorial Hospital in Rochester

Kings County

The Bay Ridge Medical Society marked its twenty-fifth anniversary on January 18 with a dinner at the Hotel Bossert

Dr Maurice Dattelbaum, president-elect of the Medical Society of Kings County, inducted the newly elected 1941 officers of the East New York Medical Society on January 6 at its annual installation meeting Dr Thomas A Gonzales, the city's chief medical examiner, was the guest speaker and discussed "Medical Aspects of Crime Detection"

Dr William Browning, who died on January 5 at the age of 85, was president of the county society in 1901 and was still a trustee at his death He was long its librarian and later directing librarian In 1898 he was one of the founders of the American Medical Library Association and was president of that important national organization from 1917 to 1919 He was the founder and first president of the Associated Physicians of Long Island

Dr Browning also made a notable contribution to the literature of medicine and was widely known for his books and his articles in technical journals

His specialty was neurology, and he was professor of neuropsychiatry at Long Island College Hospital for many years He served as state examiner in lunacy since 1893 Few physicians, declares the Brooklyn *Eagle*, have contributed as much to their chosen field as did Dr Browning

Monroe County

The following county society officers have been elected president, Dr C Stewart Nash, vice-president, Dr James K Quigley, secre-

tary, Dr William A MacVay, treasurer, Dr John J Rooney All are of Rochester

Dr James M Flynn, president of the State Society, was the guest speaker at a meeting of the Rochester Society of X-ray Technicians in St Mary's Hospital, Rochester, on January 3

Any defense emergency requiring medical aid in Rochester and Monroe County can be handled by the county medical society, it is announced after completion of a "medical preparedness analysis file" listing the available medical resources in the city and vicinity

Dr C Stewart Nash, new society president, said, "our analysis, based on data obtained from the answers to questionnaires from 546 physicians in a resource study begun last August, indicates the present and possible service which members of the society are best qualified to render"

A Medical Defense Planning Conference was held on January 16 in the Academy of Medicine auditorium, sponsored by the Medical Defense Committee, headed by Dr Clarence P Thomas.

An emergency first-aid training program for all Rochester police and firemen is planned by the safety committee of the county society The city's commissioner of public safety has promised to cooperate

New York County

The adoption by The New York Academy of Medicine of a five-year fund-raising program to increase the endowment fund of the academy by \$1,250,000 to carry on without curtailment its multifarious projects in the fields of public health and medical education was announced by Dr Malcolm Goodridge, president of the academy, in his inaugural address commencing his second two-year term on January 2

Under the plan Dr Goodridge announced, "we seek to raise \$550,000 for structural changes in the library and for greatly needed support of our annual budget During this five-year period, it is our hope and intent to increase our endowment fund by \$1,250,000, so that at the conclusion of this lustrum there may be no interruption in academy activities"

The scientific program of the evening was devoted to "Never Knowledge of the Steroid Hormones"

In order to save \$135,000 in x-ray expenses, it is charged, the government has sent 300,000 National Guardsmen to camps without adequate chest examinations—and has thereby assumed a risk of at least \$30,000,000 in future liabilities

The charge was made by Dr Ramsey Spillman, who told a meeting of the New York County Medical Society, at The Academy of Medicine, on December 23 that he was appalled by the potentialities of the government's action.

The guardsmen's chests were not x-rayed before they went into training, he said, because with the x-ray machines now available, using 14 × 17-inch film, each such examination would have cost fifty cents

Inasmuch as a new fluorograph, using a 4 × 5-inch film will be available next spring and will reduce the costs of the examinations to five cents each, according to Dr Spillman, the procedure was postponed until that time

Here is how Dr Spillman figures the liabilities the U S has risked

NEW ANTIGONOCOCCIC AGENT

No longer a secret!

It has been clearly demonstrated that Sulfathiazole, the latest contribution to modern chemotherapy, is highly effective against the gonococcus as well as several other pathogenic organisms. In some hundreds of recorded cases, gonorrhea has yielded with remarkable promptness to this thiazole derivative of sulfamidamide. According to reports already published, Sulfathiazole conforms to rigid clinical standards for successful chemotherapy of gonococcic infection. In comparison with its pyridine analogue, it is less disturbing to the patient—having less tendency to cause serious nausea or vomiting—an advantageous feature in the treatment of both ambulatory and hospitalized patients.

Incidentally, Sulfathiazole is recognized also as an outstanding anti-pneumococcic and antistaphylococcic agent.

DOSAGE. For adults, two methods of dosage have been recommended

(a) 1 Gm. (two 0.5 Gm. tablets) four times daily for five days

(b) 1 Gm. (two 0.5 Gm. tablets) four times on the first day, and 0.5 Gm. (one tablet) four times daily for the next eight days

The total average dosage by either method is 20 Gm. (forty 0.5 Gm. tablets)

Before administering the drug, read carefully the details on dosage, contraindications, side effects, precautions, etc., contained in our pamphlets (sent gratis to physicians on request)

SUPPLIED. Sulfathiazole-Winthrop is supplied in tablets of 0.5 Gm. (7.72 grains), bottles of 50, 100 and 500, also (primarily for children) in tablets of 0.25 Gm. (3.86 grains), bottles of 50, 100 and 500. For preparing test solutions, Sulfathiazole-Winthrop is available in bottles of 5 Gm.

NEW YORK, N. Y. WINDSOR, ONT

When the chests of the 300,000 guardsmen now in camp eventually are examined, it may be expected that 10 to 14 per 1,000 will be found tubercular.

This would indicate a total of at least 3,000 cases of tuberculosis among the guardsmen now in camp.

Service disability claims resulting from tuberculosis among World War veterans have cost the U S about \$10,000 each during the last twenty years.

Three thousand cases of tuberculosis among the men now in camp could therefore be expected to cost at least \$30,000,000 during the next twenty years.

Oneida County

Dr F J Rossi, retiring president of the county society, was the speaker at the annual luncheon meeting in the Hotel Utica on January 9.

Dr William Powell, eighty-four, of Utica, who died on January 9, had practiced medicine fifty-nine years.

Ontario County

Dr Benjamin R Slater, of Rochester, was the speaker at the quarterly meeting of the county society at the Canandaigua Hotel on January 14. A business meeting was held at five o'clock with dinner later.

At the scientific session, Dr Slater spoke on "Aspects of the Workmen's Compensation Law with Comments on Occupational Diseases," illustrated by lantern slides.

Dr Alfred M Armstrong was host to the Canandaigua Medical Society, on January 9 at his home on the West Lake road. Dr Philip M Standish gave the presidential address.

Orleans County

Dr Julius Layer of Lyndonville was elected president of the county society at the annual meeting in Albion on December 19.

Other officers elected were Dr James Elson, Albion, vice-president, Dr Ellen M Nicholson, Albion, secretary, Dr Edward T Eggert, Knowlesville, treasurer, Dr R. E Brodie and Dr John Dugan, both of Albion, and Dr Charles Padelford, of Holley, were appointed censors.

The fee schedule for medical and surgical services to welfare clients, as submitted by the Orleans County Commissioner of Public Welfare, was read and discussed at length. This was finally tabled, for although agreement was reached on most items, several important services, it was felt, required further discussion and conference.

The scientific part of the program was presented by Dr Richard Phillips, of Rochester, who spoke on intravenous anesthesia. Following the paper, there was an informal discussion, after which dinner was held at the Orleans Hotel.—*Reported by Ellen M Nicholson, M D, Secretary*

Oswego County

Dr F Edward Fox has been elected president of the county society for the coming year.

Other officers elected are Dr Grover C Elder, Oswego, vice-president, Dr Harold F

McGovern, Fulton, secretary and treasurer, Dr K Wood Jarvis, Oswego, censor, Dr H M Wallace, Oswego, delegate to the state convention.

Queens County

The survey of free service rendered by doctors in one Queens hospital showed that each doctor gave \$6,000 worth of service in 1939. This survey was so well thought of that the United Hospital Fund is using it as a sample to check all the hospitals in New York City.

Richmond County

The county society met on January 8 at the borough Health Center, and, after a brief business session, Colonel-Dr Louis H Bauer, of Hempstead, first vice-president of the Second District Branch of the State Society spoke on "Medical Military Preparedness"—*Reported by George W McCormick, M D, Secretary*

Saratoga County

A course of lectures on treatment of common diseases, sponsored by the Council Committee on Public Health and Education of the State Society, was arranged for members of the Saratoga County Medical Society by Dr Clayton W Greene, Buffalo, in January.

The meetings were conducted at Saratoga Hospital each Wednesday. The last two lectures in the course were given in cooperation with the State Department of Health.

Schenectady County

The county society met in the auditorium of the Nurses' Home at Ellis Hospital on January 7.

The business meeting was followed by a talk by Dr F A D Alexander, director of the department of anesthesia at Albany Hospital, on "Anesthesia for Abdominal Surgery."

Suffolk County

A forward step, unique in the public health field, says the *State Charities Aid Association News*, was taken by Suffolk County, October 29, with the authorization by the Board of Supervisors of a \$17,525 appropriation to establish a new Mental Hygiene Service in the County Health Department. This is probably the only instance in this country where such a department has assumed complete responsibility for a psychiatric clinic. The full-time staff will consist of one psychiatrist, one psychologist, two psychiatric social workers and a secretary.

The plan for the service was developed under the leadership of Dr William Ross, of Brentwood, president of the County Board of Health. "We are just as much obligated," he said, "to carry on a program for the prevention of mental illness as the one we have engaged in for the prevention of physical illness."

Westchester County

The county society met on January 21 at the New York Hospital at White Plains and listened to a paper on "Some Suggestions for the Treatment of Chronic Arthritis for General Practitioners," by Dr Loring T Swann, Boston.

The Westchester Cancer Committee announces that a course of ten lectures for physicians inter-

Hydro-Choleresis relieves Biliary Stasis

"... Will run still more swiftly if encouraged"
—Ovid

● Stasis of the bile tracts occurs in cholecystitis, cholangeitis, and hepatic dysfunction with congestion. Stasis may be eliminated by the mechanical "flushing" action of the free-flowing aqueous bile resulting from hepatic stimulation with Ketochol.

KETOCHOL is Hydro-Choleretic

The increased flow of dilute hepatic bile produced by Ketochol exerts the desired "flushing" effect, accomplishes physiologic drainage and overcomes biliary stasis.

KETOCHOL is a combination of the oxidized, or keto form of those bile acids (cholic, desoxycholic, chenodesoxycholic and lithocholic) normally present in human bile.

Average dose: one tablet t i d with or immediately after meals. Supplied in bottles of 100 and 500 tablets.

G. D. Searle & Co.

Ethical Pharmaceuticals Since 1888

CHICAGO

New York • Kansas City • San Francisco

ested in the practical application of radiation therapy in all its forms will be given each Tuesday afternoon starting on Tuesday, January 28, 1941, at 4 30 o'clock, in the offices of the Westchester Cancer Committee at 89 Pondfield Road in Bronxville.

These lectures will be given by Mrs Edith H Quimby, associate physician at the Memorial Hospital in New York City. Mrs Quimby is a recognized authority on radiation therapy, having published more than fifty papers and five books on various physical problems in relation to radiation therapy.

This course of lectures should be of great benefit, to physicians desiring to bring themselves up to date on the subject and may be looked upon as a step toward qualification in this field.

The Westchester Cancer Committee has recently purchased 173.3 mg of radium from the Manhattan Eye, Ear and Throat Hospital. The committee now has 308 mg of radium in its possession and is thus enabled to serve two clinics at once.

Admission to the course of lectures will be by written application and payment of a registration fee of \$5.00, covering the entire course of ten lectures. Interns in Westchester Hospitals will be admitted, by application, without payment of a registration fee.

Wyoming County

A teaching day program was arranged by the Council Committee on Public Health and Education of the State Society for the members of the county society, given on January 8 in the Castile Sanitarium.

The subjects discussed were the use of biologicals in the diagnosis and treatment of communicable diseases, with discussions of techniques and results by Dr Francis J Gustina, assistant professor of pediatrics, University of Buffalo, and the hemorrhagic states of pregnancy, by Dr W L Ekas, assistant professor of obstetrics and gynecology, University of Rochester Medical School.

NEW PLAN TO CONTROL MEDICAL TESTIMONY IN MINNESOTA

A new plan for control of dishonest medical testimony was officially adopted by the Council of the Minnesota State Medical Association at its regular fall meeting held September 22, at St Paul, we are told in *Minnesota Medicine*.

This plan is the result of conferences between a special committee appointed by President B S Adams, of Hibbing, and representatives of the Minnesota State Bar Association.

No change in legislation is contemplated in the plan submitted by Chairman E M Hammes, of St Paul, and approved by the Council. Instead, a permanent Committee on Medical Testimony of the Minnesota State Medical Association will be formed. Services of this Committee will be put at the disposal of any judge in the state who has reason to believe that medical testimony in any case decided in his court has deliberately deviated from the truth.

Judges will be invited to submit such cases to the Committee for investigation and study.

If, upon close investigation, it appears to the Committee that the testimony of the physician was indeed dishonest, the case will be turned over, together with all findings, to the State Board of Medical Examiners for disciplinary action.

Offenders who are thus reported to the State Board will be subject to censure and warning or to suspension or revocation of their license to practice medicine, according to the judgment of the Board.

"Honest differences of opinion exist, of course," Dr Hammes pointed out in his report. "Every allowance should be made for such differences wherever the point at issue admits of honest disagreement on the part of medical witnesses called."

"The plan is not designed to eliminate differences of opinion but to control the occasional 'shyster' physician who, like the 'shyster' lawyer, makes a farce out of justice and casts discredit upon his entire profession."

Hospital News

Hospitals Plan for Defense

WAR hospital units are now being organized by 59 hospitals and medical schools in various parts of the country, reports Dr. Malcolm T. MacEachern, of the American College of Surgeons, in *The Modern Hospital*, and he goes on to inform us that some 1,500 physicians and surgeons now on the staff of these medical schools and hospitals have applied for commissions in the medical corps reserve of the Army in order to qualify as officers of their units when and if the units, which will be equipped by the Army, are called up for active service.

An Encore

Institutions that have been asked to form units are, in general, the same that supplied units for hospital service overseas in 1917 and 1918, whose performance was so valiant and satisfactory that the War Department is now eager for preparedness of the same type from the same sources.

In the World War the units were organized through the American Red Cross and they equipped themselves. Present plans of the War Department call for 62 units, 32 of which are to be called general hospitals, 17 evacuation hospitals, and 13 surgical hospitals, each bearing the name of the sponsoring institution and serving as an affiliated unit of the medical department of the Army. Ordinarily, one field army has 10 surgical hospitals, 12 evacuation hospitals, and one hospital for convalescent cases.

The general hospitals are out of the zone of operations and about 50 of them with 1,000 beds each are required for each field army. Airplane ambulances and landing fields for them are factors to be considered in planning the locations of present-day general hospitals.

So far, the organization work has not gone much beyond selection of officer personnel, with nurses, enlisted men, and technicians to be enrolled for the units later. The purpose of organizing the units at this time is to assure the advantage of having men who are used to working together continue to do so under the stress of war conditions, if they materialize.

Three score or so of our largest hospitals and the medical schools with which some of them are affiliated are taking care of this for the time being. The remaining 6,166 hospitals cannot commit to them, however, the entire burden of national defense.

How to Help

A specific example of a way in which any hospital, small or large, can help is furnished by an institution in a small community which a couple of years ago formed a nurses' club with the idea of providing social and professional contacts for nurses in the locality who were not near enough to their nursing schools to be able to make contacts with other alumnae.

When the defense program was started, it became evident that here was a good source of additional nursing material. Several nurses who have married and ceased to practice their profession are taking refresher courses in the hospital

and are planning to register for service if needed. This idea, which was described at the hospital administrators' institute in Chicago in September may be extended to include technicians, dietitians, and other specialized personnel, as well as recently retired physicians who will be valuable for home duty in an emergency.

Must Analyze Own Needs

Each hospital must analyze the needs and possibilities of its own community and intensify its efforts to meet peacetime conditions so well that no catastrophe, be it earthquake, fire, or flood, will find it unprepared. Out of extraordinary effort to meet conditions as they arise, including the changes caused by expanding industrial activity, will come a large part of the necessary preparedness for possible war.

The Wail of the P A

(With Apologies to Ogden Nash and Arthur Guiterman)

IF YOU think *your* vocation is trying, Consider what a hospital is buying For here are the things you have to know The Superintendent told me so You have to know how to get things reasonable, Whether in stock or out of seasonable You have to buy from the local boys, For they can make a terrible noise If you don't, because all the cash that they pay in-

To community chests they expect to make hay in,

Yet everything has to be inexpensive, Whether orders are large or unextensive But here's what makes me want to shout I'm expected to know all things about
*Applicators, aspirators,
Tongue depressors, nurses' dressers,

—John H. Hayes, in The Modern Hospital*

Newsy Notes

The annual conference of the State Hospital Association will be held in New York City on May 20 to 22, 1941

Leighton R. Arrowsmith, president of the Greater New York Hospital Association, has received the following information from Dr Samuel J. Kopetzky, Colonel-MC-R-USA, Medical Division, about the investigation of hospital records of prospective draftees

1 The local boards have authority to subpoena hospital records in their investigation of claims made for or against the medical status and economic condition of prospective draftees

2 In carrying out this provision, the local board may issue subpoena to get information in the process of their investigation. In answering such subpoena for information and records, this office considers that the subpoena is complied with if you send by registered mail an abstract of the required history and a summation of the case sufficient for the local board to get the determining factors which they are seeking in the case. This material can also be delivered by a messenger or clerk in the record office

3 While the subpoena will call for the presence of the superintendent, this is to be interpreted simply that one of his representatives or the mail as above indicated is required.

Albany Hospital has made a survey of the possibility of expansion to receive war casualties and finds it could add 360 beds with no additional building program. About \$135,000 would be needed for new equipment and structural changes, and government aid would be essential.

A blood plasma bank will be installed at the Lewis County General Hospital

Buffalo Children's Hospital has laid a new type of rubber flooring in its surgery suite. It contains a wire mesh, grounded to carry off electricity and to prevent sparks that sometimes cause anesthetics to explode

The army hospital at Fort Ontario, Oswego, is being enlarged and newly equipped to receive

over 100 patients. Twelve surgeons are on the staff

The financial plight of New Rochelle Hospital has become so distressing that a special campaign is on to raise funds to pay off mounting debts for operation of the institution, says a local paper

One of the items that has added to the gravity of the situation is the fact that the hospital has been unable to pay the bills of local merchants. This item alone amounts to about \$70,000

A major cause of the plight is the fact that 1,683 indigent and destitute patients received service from the hospital in the past year at a cost of \$155,889. For these services the hospital received only \$71,342

The three State hospitals in Suffolk County have a total of 5,682 aliens out of 22,380 patients, which is more than half the estimated 10,000 aliens registered throughout the county during the past four months, it is learned. Pilgrim State Hospital at Brentwood, which has 9,060 patients, led with 2,487 aliens. At Central Islip State Hospital officials reported there are 2,005 aliens out of 7,330 patients, and Kings Park State Hospital has 1,100 aliens among 6,000 patients.

The Mary Imogene Bassett Hospital at Cooperstown is offering the general public a short series of Sunday afternoon talks on outstanding diseases and newer methods of treatment.

Only two maternal mortalities out of 1,400 cases have occurred at the Good Samaritan Hospital in Suffern in six years

William T. A. Webb, of Sidney, Delaware County Member of Assembly, has indicated that he will propose a bill at the legislative session to make the care of patients at the state tuberculosis hospitals a state charge. Mr Webb's measure would attempt to make the change retroactive

Delaware County supervisors have indicated they will await the outcome of the action by Chenango and Madison counties in fighting the payment of such charges by the Homer Folks Hospital at Oneonta. The claim against Delaware amounts to about \$56,000

These counties maintain that the bills of the hospital are illegal and also that they have no information as to whether the individual charges are proper claims against the counties. Otsego concurs in this feeling but has authorized the payment, when audited, of \$51,000 toward a total claim of over \$100,000

A group of doctors headed by Dr M. A. Mason and B. L. Lurie has completed arrangements for conversion of the Kew Gardens Hotel, Kew Gardens, Queens, into a general hospital to meet growing demands in Queens for hospital and medical facilities. More than \$200,000 will be spent in modernizing and equipping the present structure for opening in February

Improvements

St. Francis' Hospital in Poughkeepsie is planning a \$100,000 addition.

A proposal to build a \$200,000 general hospital of 132 beds on the Rosenbaum estate at Roslyn has been taken under advisement by the Village Board. The hospital will be one of the largest of its kind in this area, according to the tentative plans. The offer was submitted by Dr. Louis S. Bardoly, of Cleveland, through his architect, Herbert Tannenbaum, who said "Every feature of a large city hospital will be included and all efforts will be made to take it out of the private class and make it a community affair."

Work has started on the six-story addition to St. Clare's Hospital, adjoining its present building on 52nd and 53rd streets, between Ninth and

Tenth avenues, Manhattan. It will increase its present capacity to 300 beds.

The Father Duffy Post of Catholic War Veterans has presented an iron lung to Misericordia Hospital.

A 20-bed hospital has opened in Canton.

Vassar Hospital, Poughkeepsie, is adding a new dietetic laboratory.

University Hospital of the Good Shepherd, Syracuse, is undergoing extensive renovation.

KEEP ON PITCHING

"Keep on pitching, doctor!" exclaims the editor of the *Kansas City Medical Journal*, Dr. E. H. Skinner. "There are nine innings to every ball game," he reminds us. "This old world has seen a lot of battles. And it just keeps on turning around. The sun still has a chance to shine every day. There have been a lot of pestilences that have taken more people than battles. Thanks to doctors, pestilences are no more. Possibly we should try a little medical research upon war or upon ruthless maniacs who are deluded with the idea that power and force are commendable items of human behaviorism."

"This European cataclysm makes a lot of our individual, and even governmental interests look very small and immaterial in comparison. But there are reasons why we should not give up any of our objectives. We are going to have to give up a lot of things but let us hang on to our priceless heritage of Freedom just as long as we live. Our forefathers fought for the priceless heritages of our democracy and plenty of them died for their ideals. This world situation has not yet reached any such tragic outlook but we are going to have to sacrifice so many of our worldly and comfortable conveniences that a lot of weak sissies are going to feel you are taking their life's blood."

"It would not be surprising if the politicians took advantage of the present emergency to try to regiment the medical profession as a defense measure. You must keep on pitching, doctor, for these politicians are wise boys and they know how susceptible your clientele is to that old emotional appeal for something more for nothing. We are going to have to give and give up. But we must keep up our courage and our freedom and our priceless heritage of democratic ideals."

"Doctor, you will never get a chance at another game as fine as it is played in America. So, keep on pitching, doctor!"

DIAGNOSIS—LAZY FEMALE

He said—sweetly
Your nerves are slightly out of kilter
Your liver's just a little off
If you'll go home and get some rest
Your head upon a pillow, soft
And every hour chew one of these
I think that they should stop that pain
But if they don't just call again

He thought

Boy, but I could go to work on you
I'd have you scrub your face first thing
Fat old hen, all painted up, you look like sin
And every morning bright and early
I'd walk you forty blocks, old girlie
And feed you spinach, squash, and lettuce
Your hide, gee, what an awful mess that is
I'd put a corset on you honey
For when you walk, you shake so funny
Take off those shoes—for love of heaven
She's got size 4's, they should be seven
In fact I'd do a lot for you
If you would only let me
But if I told you what I thought
Nobody'd have to bet me
That you'd go see Doc Jones instead
And pay him to put you to bed,
And as you're going to pay somebody
It might just as well be me
—Ruth Elliott in *Utica Academy of Medicine Bulletin*

NO WISH TO SEEM QUEER

"You inherited quite a nice little fortune," said the doctor.

"Yes," replied the fortunate youth.

"I suppose you will pay a lot of your debt now?"

"I had thought of it, but I concluded to make no change in my manner of living. I don't want to be accused of vulgar display."—*Case and Comment*

Mr. Haveadrink is being examined by his physician.

Dr. Sorry: "I can't find any cause for your troubles. I think it's due to drinking."

Patient: "Well, maybe I had better come some time when you are sober."—*Med. Record*

How eye accidents are prevented in industry, through education of workmen and the use of goggles, masks, and other protective equipment, is dramatically portrayed in *The Eyes Have It*, a new sound slidefilm sponsored by the National Society for the Prevention of Blindness.

What is the Physicians' Home?

The Physicians' Home is not an academic experiment. It is a reality. It concerns itself with the future and old age of human beings,—members of our profession. The Physicians' Home provides a home and maintains comfortable standards of living for its guests.

The validity of our worthy charity is not to be looked for in stone, but in the actual benefits now utilized by members of our own profession. It is a challenge to all of us to accept the responsibility for helping those less fortunate than ourselves. Please cooperate.

Public Health News

Sulfapyridine to Be Distributed by New York State Department of Health for the Treatment of Pneumococcic Infections

EFFECTIVE January 23, 1941, the New York State Department of Health will distribute sulfapyridine for the use of registered doctors of medicine and hospitals in the treatment of pneumococcic infections in *patients for whom the purchase of the drug would prove a hardship*. Packages of 50 tablets (0.5 Gm each) may be obtained upon request from certain of the regular laboratory supply stations. A list of the supply stations designated for this purpose will be provided each physician through a memorandum from the District State Health Officer in his area.

The drug will be dispensed in bottles bearing the manufacturer's label in a form which may be detached, leaving on the package as it finally reaches the patient, a partially blank label upon which the physician may write his instructions. The label will, however, carry an identifying number which will not be intelligible to the patient. It is recommended that the manufacturer's label, bearing the name of the drug, be detached in order to discourage the possibility of self-medication should any of the drug be left after treatment of the case for which it was prescribed.

How to Obtain the Drug

In order to obtain the drug the physician should sign a request slip similar to that now used for antipneumococcus serum, or should submit a signed letter of request containing the name and address of the patient, date of onset, bacteriologic findings, and place of examination, if done, or he should provide the laboratory custodian with such information if the request is telephoned. This information must be supplied for each package withdrawn.

The drug so distributed is intended for the treatment of pneumococcic infections only. However, prior sputum typing or other identifying bacteriologic examinations will not be required. Such examination, nevertheless, is still recommended as an essential of good practice. Certification of relief status or medical indigency will not be required but physicians are requested to cooperate in limiting their requests in order that the supply may be conserved for those who most need it.

In instances where the physician or hospital institutes sulfapyridine treatment and temporarily supplies the drug from a private stock, such private stock may be replenished in an equivalent amount from the supply subsequently withdrawn in the name of the patient.

Record of Treatment

For sound administrative practice in the distribution of this drug as well as the continued production and distribution of antipneumococcus serums, brief clinical reports on the character of the case and the response to the therapy given are essential. In order to bring about the greatest simplification, the serum report form previously used has been entirely revised, the questions reduced to a minimum, and a section added for use in cases receiving chemotherapy. This new form (7-f) will, therefore, serve for cases receiving State distributed serum, State distributed drug, or both.

Upon completion of treatment, the record form (7-f) should be returned to the District State Health Officer within whose district the case resides or, in accordance with instructions from the District State Health Officer, to the County or City Health Officer in certain instances. This represents a change from previous practice with serum reports in which the forms have usually been sent directly to the Division of Laboratories and Research of the State Department of Health in Albany.

Sulfathiazole

It is expected that a similar plan for the distribution of sulfathiazole will be undertaken as soon as this drug has been accepted by the Council on Pharmacy and Chemistry of the American Medical Association.

NEW YORK STATE JOURNAL OF MEDICINE

Copyright 1941 by the Medical Society of the State of New York

VOLUME 41

FEBRUARY 15, 1941

NUMBER 4

Editorial

Elephant's Child

On July 15, 1940, in the military medicine number of the JOURNAL, we published an editorial on the subject of physicians' life insurance in war time. The editors' purpose was to provoke discussion of this moot subject so vital to the welfare of those medical men and women who were about to enter the military and naval services.

At the time that this editorial was published, very little information was to be had as to the probable effect of our peacetime training mobilization on the existing structure of physicians' insurance contracts. We felt, however, that to raise the issues, which developed from questions being asked us by our correspondents, might in the course of time provoke authoritative information from some informed source. We also felt that being the first medical publication to print a military medicine issue, our role should be that of the elephant's child who, if you will remember, was "full of 'satable curiosity'." He asked his broad aunt, the Hippopotamus, why her eyes were red, and his broad aunt, the Hippopotamus, spanked him with her broad, broad hoof, and he asked his hairy uncle, the Baboon, why melons tasted just so, and his hairy uncle, the Baboon, spanked him with his hairy, hairy paw. And still he was full of 'satable curiosity'. He asked questions about everything that he saw, or heard, or felt, or smelt, or touched, and all his uncles and his aunts spanked him. And

still he was full of 'satable curiosity!'"*

Well, *in loco parentis*, the *Connecticut State Medical Journal* spansks us again editorially in its January, 1941, issue, to wit:

"The New York State Journal of Medicine has recently given prominence to the discussion of the physician's life insurance in war time. In order to intercept any false interpretations or deductions a clarification of the subject is imperative. The voice of experience and, may we add, of authority, which the New York editor is pleased to ascribe to us, should logically come from Hartford, the insurance center of the nation. The payment of all types of insurance premiums becomes a serious problem for either physician or layman in the event of military service. Insurance carriers of accident and health policies are ruling that such policies shall continue in effect only provided that the insured remains within the United States or Canada, that he does not enter the air service, and provided that this nation does not engage in actual warfare. Life insurance is, of course, only one of the serious financial problems facing physician or layman who enters military service. He may be encumbered with mortgage payments on his home, monthly installments on his automobile or gas refrigerator, or interest on financial loans. The pay of a first lieutenant or of a captain will undoubtedly fall far short of the necessary income to meet these obligations.

"Our friends in New York commit a fundamental error when they reason that to borrow on a life insurance policy represents the insured's own money loaned back to him by the insurance company. A man does not borrow 'his own' money when he borrows on a policy, but, rather he enters into an agreement with the investment department of the insurance company whereby this same company agrees to invest some of its

* Kipling R. Just So Stories Garden City Long Island, New York Doubleday Page & Co 1915

Woman's Auxiliary

To the Medical Society of the State of New York

APPROPRIATELY, once a year it seems wise to bring to the attention of our members through this page the importance of not only subscribing to but also the reading of medical literature. You have four publications for reading, reference, and study—the *Bulletin*—the publication of the Woman's Auxiliary to the Medical Society (see November 1 issue of the *JOURNAL*), *Hygeia*, the organization section of the *J. A. M. A.*, and this page in the *NEW YORK STATE JOURNAL OF MEDICINE*.

Our national president, Mrs. V. E. Holcombe, prepared by special request a splendid booklet called "Why read the *Bulletin*?" Excerpts are as follows: "Do you want to know more about the program of the Auxiliary and the working of each of the several Committees? Do you want to know why we promote the sale of *Hygeia*? Do you want to know why we feel it our duty and privilege to emphasize a Health Program, encourage a Public Relations and a Legislative Program? Do you want to know what the Auxiliary stands for? Why so many fine intelligent women are giving so much of their time to this organization? Why the doctors themselves encourage the growth and expansion of our activities? Read the *Bulletin*, the Auxiliary Digest. Become informed on the whole Program of the Woman's Auxiliary to the American Medical Association and its component Auxiliaries."

The *Bulletin* is our medium of information. The members should read it because it conveys to them knowledge of what other members are doing. They may read that there are others who have problems, and the way they were solved. A tie of interest and understanding is formed through the channels of information concerning each other. The *Bulletin* gives the main facts about the activities in which our organization is engaged, and the progress thereof. It presents the essential features of what is transpiring.

We feel that you and all readers will be amply repaid by having firsthand knowledge of the doings of the finest profession in the world and its Auxiliary. With this information and inspiration we feel that we shall all be more worthy members of the Woman's Auxiliary to the American Medical Association. Our quota for New York State is 350 subscribers, to date we have 84. Subscriptions may start any time. *Is yours in?*

Mrs. Joseph P. Lesko, our state chairman, writes: "What do you do with your *Hygeia*'s?"

"When this month's *Hygeia* arrives place last month's on your private desk. If you have any extra sample copies, do the same with them. In the course of your treatments your patient may want something to read—hand him *Hygeia*. Or, while you are sterilizing a 'Hypo' or instruments he will pick it up and glance through it. As he walks out hand it to him to take home. Surely he will not read it through in your office. And, in what better way could you get it to the rest of his family? The layman thirsts for medical knowledge. He will read every medical article in the papers, why not in *Hygeia*? He will. Once he finds out where he can get good everyday horsensense he will come back for more. Is it not also possible that brother Bill, of draft age, may be interested in last November's 'Aviation Medicine'? If young Jack sees those football players, will he throw it aside? Not on your life! Where could he get a better argument to show mother? And, incidentally, is it not quite possible that mother will bring Jack over to see you to find out whether or not he is physically fit for the game? If you do not read *Hygeia* yourself, glance through the index. You will notice the article on 'Teeth.' Only last week Mrs. Jones was in to consult you about her child's teeth. Have your secretary wrap up the November issue, put a three-cent stamp on it and mail it to her. She will appreciate it. First, however, in ink, write the number of the page on the cover and underline it. At the bottom write 'You may subscribe through your local Woman's Medical Auxiliary.'"

Attention Auxiliary Members!

"Where is the Annual State convention to be held?" Headquarters at the Hotel Statler, Buffalo, New York. "When?" April 28 to May 1, 1941, inclusive. "Who is Convention Chairman?" Mrs. Carlton E. Wertz. Any information may be obtained from her at 95 Parker Avenue, Buffalo, New York. Mark the time and place on your calendar at once. Everyone needs a vacation and a change at this time. Buffalo with its romantic associations offers much to the busy doctor and his wife. This famous city is boasting of a brand new Convention Hall and new Music Hall. Each issue of the *JOURNAL* will contain added news. Be sure to watch our page for the attractions to be afforded the Woman's Auxiliary by Mrs. C. Wertz and a committee.

TO PROVIDE FOR THEIR NEEDY

The Illinois State Medical Society has established a Benevolent Fund to provide for needy members or their widows or widowers and to be administered by a Committee on Medical Benevolence. One dollar a year will be paid into the fund from the dues of each member, and those in need will receive "regular" monthly benefits not to exceed \$25 to \$30 per month in any one case. The Illinois plan closely resembles the one which has been operating in Pennsylvania for thirty-seven years.

UP AND ATOM!

Someone has written: "The structure of a molecule seems to the average man to be of little importance in its relationship to the saving of human life. When, however, a chemist moves one of the components of a molecule from one point in its structure to another, and thereby develops a drug with specific virtues against a disease that has devastated man for the last four centuries, the interior elements of a molecule then become of considerable interest."—Quoted in the *Journal of the Tennessee Medical Association*.

cannot make the prepayments called for, which means that the vital problem of widely distributing medical care is not touched. The patient who can prepay must choose a (participating) doctor, though that doctor may not have the privileges of a good voluntary hospital

The *Times*, we feel, is perhaps a little oversentimental and under-informed in stating that "the vital problem of widely distributing medical care is not touched"

at least in the State of New York. The problem admittedly has difficulties, all of which are not to be solved by prepaid medical expense insurance. "Families that must live on \$1,000 a year or less" and "cannot make the prepayments called for" appear to the *Times* to be beyond the reach of widely distributed medical care, if we understand correctly the printed word.

We are glad that the *Times* has brought this matter to light. For some time there has been on the statute books of this state—Public Welfare Law Article X, section 83—a statement of the responsi-

bility of public authority for providing medical care. We quote

The public welfare district shall be responsible for providing necessary medical care for all persons under its care, and for such persons otherwise able to maintain themselves, who are unable to secure necessary medical care, except insofar as, in cases of communicable disease, that duty may be imposed upon the health officer by law or the state sanitary code. Such care may be given in dispensaries, hospitals, the person's home or other suitable place.

Perhaps this is news to the *Times*, perhaps not. At any rate medical care, the *Times* will note, will be provided for "persons otherwise able to maintain themselves," by a beneficent state government. Surely the persons "that must live on \$1,000 a year or less" would fall into the category of persons otherwise able to maintain themselves but who are unable to secure necessary medical care? In that case why these tears? Can the *Times* be seriously questioning the good faith of the state government? Tsk! Tsk!

Socialism vs. Sociability

How social is socialism? The obvious answer seems to be about as companionable as the socialists! In the recent past, socialism was perhaps farthest advanced in Germany, Austria, the Irish Free State, and the Scandinavian countries. In 1936 France came under the control of a socialist government for better or worse and Spain overthrew its semisocialist government in favor of fascism.

Somehow the cooperative movement among peoples seems to revert to the old-fashioned practice of blood-letting as a cure-all, a practice discarded as inefficient, ineffective, and outmoded years ago by the medical profession. Hence it has been with some misgivings perhaps that physicians have watched the carefully fostered growth of socialism in this country. For physicians are really very sociable people. They get around among the folks quite a lot.

Among the people of this democracy the physicians circulate—among the friendly, sociable people riding in automobiles, laughing, dancing, going to church, voting in free elections, eating butter, drinking beer, arguing about any and everything under the sun, listening to radios, attending prize fights, working to produce useful and beautiful things, living together in sociability. Among these people physicians move yet awhile.

And in their hearts they wonder about this thing called socialism, this cooperative movement which has produced all the fine things of life in modern Europe, the fine burning of books, the magnificent bombings of Ethiopians, the exquisite torturing and murder of Jews, the elegant collapse of France, the splendid civil war in Spain, the sublime demolition of architectural landmarks in Britain, the

money with him, provided he pays interest for the use of it. This process is entirely comparable to the investment of money by the life insurance company in real estate and in investment securities, but in any event the company must realize a return on money invested in order to maintain solvency. Borrowing money from an insurance company by an individual is no different from borrowing money from a bank. In the second instance the bank requires collateral of securities, or other tangibles, while the insurance company accepts a life insurance policy as collateral up to the amount of reserve which has accrued against the policy.

"Automatic extension of insurance at the face value of the policy for a period dependent upon the amount of cash reserve in the policy has been suggested as a solution of the physician's difficulties in meeting premium payments. The question is, why limit the moratorium to life and accident premiums? It could as fairly be applied to any current debt or obligation incurred by any individual who may become a part of the fighting forces of the United States. What would be the result upon the economic system if such a procedure became legalized? Let us not forget that a life insurance policy may be paid for in full if the insured so desires. Furthermore, if a continuation of the payment of life insurance premiums is not desired for any policy, the insured is protected through paid-up insurance for 100% value of all premiums paid up to the time of the cessation of premium payments and, therefore, no further premium payments need be paid.

"Our neighbors from New York, 'to provoke discussion of this subject,' have suggested a transfer of insurance from private to government control. This invites the entrance of the government into the field of insurance. During World War I the government sold cigarettes at seven cents a package at army posts, while the same product was sold elsewhere at fifteen cents a package. How was the difference in selling price made up? How will the difference between the premium charged for government insurance and the actual cost of the insurance to

the government be met? The answer, obviously, is by taxation toward which everyone contributes. How far do we wish to permit the government to be projected into private enterprise? If it is going into business at all, why not into all fields? Can the government handle any business as efficiently as is possible under good private management? How great a degree of efficiency in business may one expect from the government when the results of lack of efficiency, lack of judgment, lack of foresightedness, and lack of honest endeavor can always be compensated for by an increase in taxes? Will the change of operating personnel under government control due to the change in administrations tend to keep the level of efficiency as high as under private enterprise?

"It requires no deep study on the part of well informed citizens to realize the repercussions of the T V A experiment where taxation is concerned. Private enterprise is based on the premise, 'be successful or you perish,' and that is an impelling incentive for the achievement of success. Such an incentive would be non-existent under government control. Government securities do not in themselves yield sufficient income to insure the solvency of any insurance organization. The government itself can make up this deficiency only by increased taxation, but the source of supply will fail if business is choked by a moratorium and the natural flow of money necessary to carry on all business is thereby reduced.

"There is most assuredly no novel or magic way of providing for life insurance premiums of those engaged in the business of military training. The mysteries of the Aladdin-like legerdemain performances in Washington have long since been divulged. Financial obligations, including life insurance premiums, cannot be suspended nor can protection exist for the physician only insofar as he pays for it. The hard way remains the only way for us, as for countless others in the disrupted world of today."

And still we are full of 'satisfiable curiosity!'

The Medically Indigent

We are indebted to *Medical Economics*¹ for the following contribution to the matter of prepayment plans for medical service:

The Bronx County (N Y) Medical Bulletin points out that premiums for sickness insurance are so steep as to be suited only to those in high income groups. "Organized medicine is not interested in establishing voluntary in-

urance plans for the high income brackets," the Bulletin declares. "This class of patients is financially capable of paying for medical service and is the backbone of present medical practice. Why organize insurance plans jeopardizing the little practice still left with us?"

To which the *New York Times*, in a recent editorial, adds

Families that must live on \$1,000 a year or less cannot be reached because they

"HEALTH INSURANCE" VERSUS "SICKNESS INSURANCE"

This controversy began with the publishing of Dr Haven Emerson's letter in the January 1 issue—Editor

January 17, 1941

To the Editor

The term "Health Insurance" has been challenged as fallacious and misleading. In order that there be no misunderstanding as to the intent and meaning of the phrase, we should properly investigate its use and definition and compare it with the proposed term "Sickness Insurance."

1 In the first place "Health Insurance" is used in the same sense as "Life Insurance," which surely does not guarantee life, but does insure payment of certain sums when death occurs. In the same way "Health Insurance" makes no guarantee for health but promises certain services or payment should illness occur.

2 In the second place, it is hoped that group insurance will make the path easier to the physician's door. When preventive medicine can be more readily received, and when periodic physical examinations and prompt treatment when needed are the order of the day, can there be much question that the insured group will enjoy better health than a similar uninsured group?

3 Third and last, it is more worthy to use a positive rather than a negative term. Health may be good or bad. As defined by Funk and Wagnall's dictionary, health means "soundness of any living organism, also physical condition, good or ill." Also, "Health Insurance" is listed in standard dictionaries, but nowhere is there a definition or listing of "Sickness Insurance."

The *Quarterly Cumulative Index Medicus* from Vol. I (1927) to Vol. 27 (1940) has under the heading of "Insurance," Accident, Health, Life (and occasionally Social, Physicians', and Fire). "Insurance, Sickness" appears never to be used at all by the Index, but "Insurance, Health" is by far its largest category under Insurance.

Therefore, by definition, meaning, and common usage, the term "Health Insurance" is accurate, honest, and legitimate.

Very truly yours,
ELINOR B HARVEY
DONALD K FREEDMAN

January 20, 1941

To the Editor

Inexact terms and lack of definitions are common causes of profitless controversy and confusion of thought. If the medical profession is to continue to deal honestly within its own ranks and with the public, it will wish to use terms that are neither ambiguous nor deceptive.

There is much to be said in favor of insurance to meet the cost of medical care in sickness especially if on a voluntary basis. If such insurance is sold to the public as "Health Insurance" the insured will expect health which cannot be promised or paid for on any basis so far undertaken. The first step toward useful discussion is a correct use of terms.

1 Fire Insurance, Accident Insurance, Burglary Insurance, Sickness Insurance are terms implying financial protection against the costs of the hazard named.

Life insurance is an investment in benefits to others than the insured person, who pays for them during his life.

Sickness insurance, a term correctly describing systems, voluntary and compulsory, in effect in continental Europe at least since Bismarck's time, was replaced in England for political persuasiveness by Lloyd George about 1912 to obtain support for his compulsory participating plan for medical care for wage earners. The term "Health Insurance" is widely used in this country for the same purpose. Neither the purpose, which is to persuade people to vote for something they will not in fact receive, nor the term itself as descriptive of the purpose for which the insurance fund is created justifies our use of the phrase "Health Insurance" in medical discussions among ourselves or with the laity, except to warn against its incorrect and unpredictable implications.

2 Group or individual insurance to meet the cost of periodic medical or health examinations or examinations for diagnosis and early treatment of "pre-clinical" states of disease may or may not contribute to the health of the individual, according to the patient's understanding and cooperative ambition to achieve, maintain, or improve his health. This cannot be insured either for or against. This is not included among compulsory "Health Insurance" benefits in England. There is no evidence in this country or abroad that insurance schemes to meet the cost of care in sickness have been an important factor in the health status of the people generally or of the insured group. Nor has the misnamed "Health Insurance" scheme in England brought to the insured a superior or adequate quality and range of medical care in sickness.

3 Sickness insurance will win its way into dictionaries and ultimately in the *Index Medicus* when it is clearly understood to describe something definite, exact, correct as defined, and quite different from "Health Insurance" as intended by its current promoters.

Whatever our language or national inclinations or traditions, we must admit that *Krankheit Versicherung* has the precise meaning of sickness insurance. *Gesundheit Versicherung* is something different and nonexistent. The British adopted a new name for an old thing without altering its essence or quality.

There are no health services offered or provided for under the "Health Insurance" scheme in England. Insurance is not paid when health is lost. The cost of sickness is paid for. The insured determines when he or she is sick and demands attention. The insured have no investment in health and their insurance does not give them any better health.

Very truly yours,
HAVEN EMERSON, M D

esthetic conscription of labor, the graceful starvation of human beings, the imposing exile of human herds, the superb walling-in of the "begats" of Abraham

And in their minds they ponder about this thing called socialism, this cooperative movement in this hemisphere which commences now to produce many things in America. Social Security, and guns and tanks, compulsory sickness insurance, and men marching in uniform in

peacetime, and debt, and warplanes, the socialization of medicine, and warships, torpedoes, bombs, and lease-lend bills and taxes for the happy folk to pay so that they can be more expeditiously socialized in the shadow of democracy

How social is socialism? Your guess is as good as ours. You have eyes to see and ears to hear with. Look in the open book of history, listen, and you will hear the dull tramp of marching feet

Hearing Aids

About five million people in the United States are so hard of hearing as to require some sort of hearing aid. Their problems in this respect are discussed elsewhere in this issue by Dr. Thomas H. Halsted, F.A.C.S., emeritus professor of otolaryngology, Syracuse University College of Medicine, now resident in New York City.

For the first time, we are informed, there is now established here a means whereby the hard of hearing may be advised by competent medical authority *and scientific individual adaptation may be made of the various hearing aids.* Formerly, advice on these matters has been largely a service rendered to patients by manufacturers' representatives and such of the laity as considered themselves to be competent advisers

by virtue of using some mechanism themselves.

The science of acoustics has made such rapid strides in recent years that it has become increasingly impractical for many medical men to devote their entire time to the study of the physical, electrical, and chemical technology which has entered into the production, operation, and adaptation of the many devices now on the market.

When, as in Dr. Halsted's case, a medical man can make available to the hard of hearing a consultative service based on this wide study of apparatus plus a physician's knowledge of the anatomy, pathology, and physiology of the ear, we believe that again a definite advance has been made in the public service rendered by the medical profession.

"Shuffle off to Buffalo"

is the tune we recommend for the latter part of April, for, on the twenty-eighth, the 1941 Annual Meeting of the Medical Society of the State of New York will convene there. The dates are from April 28 through May 1. The headquarters will be at the Hotel Statler and you are urged to make your reservations *now*.

The scientific program will be particularly outstanding this year and we hear that the banquet is to be an occasion that no Society member will want to miss.

Start "shuffling" your spring dates now so that you will be in Buffalo on April 28.

ARSENIC AS A POSSIBLE CAUSE OF SUBACUTE ENCEPHALOMYELITIS

A Correlation of Chemical, Clinical, and Histologic Observations

ARTHUR D. ECKER, M D , Ph D (Neur), Syracuse, New York

THE present study resulted from the observation that the clinical course in cases of subacute, fatal encephalomyelitis frequently seems attributable to the continuous action of some toxic agent. Considerable amounts of arsenic were found in the brain in most instances in which that tissue was available. It is proposed in this study to consider the possible significance of these facts by correlating the clinical, pathologic, and chemical features in these cases.

Review of Literature

Under modern conditions there is the growing likelihood that large numbers of people exposed continuously to arsenic from a multitude of legitimate everyday sources may be slowly poisoned through its cumulative effects.¹⁻⁴ Therefore, one must necessarily agree with the statement⁵ that, confronted with an individual sufferer in a complicated and irresponsible society, the detection and control of intake of arsenic are perhaps impossible at present. Furthermore, under living conditions of the present day it is probably impossible to remove a patient from all contacts with arsenic.²

It is not generally recognized that in chronic arsenical poisoning there is frequent evidence of involvement of the brain. However, a review of the European⁶⁻¹⁰ and American¹¹⁻¹⁴ literature on the subject of arsenism shows that cerebral signs not only are present but also are often the leading clinical features of the disease. These symptoms are primarily headache and fatigue, both bodily and intellectual. This clinical picture is not unlike neurasthenia.⁶ However, additional symptoms that may be present include dizziness, restlessness, excitability, or mental dullness. It is, therefore, beyond question that chronic arsenical poisoning is manifested frequently by cerebral symptoms. Unfortunately, in none of the preceding reports of such cases was microscopic study of the brain reported.

This essay was awarded the Merritt H. Cash Prize at the 1940 Annual Meeting of the Medical Society of the State of New York. The research was carried out at the Mayo Foundation for Medical Education and Research, Rochester, Minnesota.

From the Syracuse University College of Medicine.

For over one hundred years¹⁵⁻¹⁹ there has been continual dispute as to whether or not arsenic is a normal constituent of the human body. However, the opinion of the majority of modern toxicologists²⁰⁻²² is epitomized by Kunkel²³ who stated that so-called normal arsenic, if it exists at all, is so extraordinarily small in amount (hundredths or even thousandths of a milligram in an entire organ) that it is not of forensic significance, whereas quantities a hundred or a thousand times larger are of significance.

In cases of chronic poisoning from a single large dose of an inorganic arsenical compound, the central nervous system, as well as the long bones and the hair, contains more arsenic than the so-called primary depots—the gastrointestinal canal and liver.^{24,25} The relative arsenical content of the various organs in a case in which inorganic arsenic is received continuously or intermittently until death occurs lies somewhere between that associated with acute poisoning and that associated with chronic poisoning following a single large dose.²⁶

However, following the continued administration of the organic compounds of arsenic (specifically, arsphenamine and its derivatives), amounts less than 0.1 mg. of arsenic per hundred grams of fresh tissue are generally to be found in the brain.²⁷⁻³² The major group of cases which are exceptions to this general rule is represented by the cases of so-called hemorrhagic encephalitis.³¹

The pharmacodynamic effects of the trivalent compounds of arsenic, both inorganic and organic, include direct interference with the oxidation of tissues in general,³³⁻³⁵ and widespread paralysis of arterioles, capillaries, and venules.³⁵⁻³⁷ This vasomotor paralysis subsequently aggravates the embarrassment of tissue respiration.

The effects on the brain and spinal cord of arsenical compounds of all three groups, inorganic,⁴³⁻⁴⁵ organic pentavalent,⁴⁴⁻⁴⁶ organic trivalent,⁴⁷⁻⁵³ are identical. These effects are what might have been expected on the basis of the pharmacodynamic effect of these compounds. The primary interference with tissue oxidation is marked by nonspecific

ERRATA

Workmen's Compensation

In the February 1, 1941, issue of the JOURNAL there appeared on page 259 two errors which need correction

In the second paragraph, line 1 should read "It should be noted that the C-4 report must," etc, instead of C-14

In the third paragraph, line 4 should read "The law states that the C-14 report," etc, instead of C-4

The corrected report is published below

February 5, 1941

DAVID J. KALISKI, M D
Director

WORKMEN'S COMPENSATION

We have been informed by the Director of Workmen's Compensation of the Department of Labor that many physicians throughout the state are not yet familiar with the amendments to the Workmen's Compensation Law which became effective on July 1, 1940. These were published in the NEW YORK STATE JOURNAL OF MEDICINE, June 1, 1940. The attention of physicians practicing under the Workmen's Compensation Law is again directed to these amendments, and they are urged to comply with them.

It should be noted that the C-4 report must now be forwarded to the employer or insurance carrier and the Department of Labor, within fifteen days instead of twenty days as heretofore. This report should be notarized, but physicians are urged not to delay it if a notary is not available. The C-104 form is reportable within forty-eight hours.

The new progress report (C-14) should be sent to the employer or insurance carrier and the Department of Labor in all protracted cases every three weeks. The Law states that the C-14 report should be submitted "when requested" by the employer or insurance carrier, but it is advisable to submit such reports, even though not

requested, at regular intervals, in order to familiarize the employer or insurance carrier with the progress of the patient if the medical care continues beyond the first four weeks or so.

Another amendment, effective July 1, 1940, gives to the Industrial Board the right to assess the cost of medical care against a noninsured employer. Physicians treating claimants whose employers fail to carry insurance should submit bills for medical service directly to the Department of Labor, care of the Industrial Board, 80 Centre Street, New York City, and send a copy of the correspondence and bill to this office.

Workmen's compensation committees or boards throughout the state are urged to bring the above changes to the attention of physicians at the regular meetings of the county societies and by publication in local bulletins.

The various forms (C-104, C-4, C-5, C-14, C-27) are available on application to the local county society office. Forms are obtainable by the societies upon application to the Department of Labor, Albany and New York offices. Physicians should not apply directly to the Department of Labor for blank forms.—David J. Kaliski, M D, Director

clusive (Tables 1 and 2), therefore, represent instances of known arsenical poisoning

Subsequently, a large miscellaneous group of cases listed in the neuropathologic files available under the heading of "Encephalitis" was considered. First, the brain tissues that had been preserved in formalin were tested for the presence of arsenic, and the finding of 0.1 mg. of arsenic per hundred grams of tissue was considered significant. Instances in which the brain contained such amounts were designated positive cases. Other instances in which less than this amount of arsenic was present were called negative or control cases (Cases 14 to 37). After the presence or absence of arsenic had been determined, the clinical records were studied for evidence of the presence of syphilis. In the event that there was any clinical evidence of syphilis the case was withdrawn from our consideration in order to avoid unnecessary confusion. The prevalence of the use of arsenical compounds in the treatment of syphilis would interfere with proper interpretation of the chemical findings, and the possible presence of syphilitic meningoencephalitis might complicate the interpretation of the neuropathologic findings. The remaining positive cases constitute Cases 44 to 55, inclusive (Tables 3 and 4), in our series and represent the main object of this study.

Chemical Methods—For determining the presence of arsenic in the brain and liver, Osterberg's¹⁰⁰ modification of the electrolytic Gutzeit apparatus was used. Five grams of tissue were used in all of the determinations on brain and in all except two or three of the determinations on liver in which only smaller amounts of tissue were available.

It was important to determine whether the arsenic in the brain might have resulted from embalming fluids. Accordingly, samples of the eight embalming fluids used by all the undertakers who embalmed the brains in these cases were tested for their content of arsenic. One specimen did not contain arsenic. In 1 case, there was 0.02 mg. of arsenic per hundred cubic centimeters, in 4 cases, 0.04 mg. per hundred cubic centimeters, and in 2 cases, 0.4 mg. per hundred cubic centimeters. If the maximal concentration found in these cases had been used—that is, a solution containing 0.4 mg. of arsenic per hundred cubic centimeters of embalming fluid—and if 1,000 cc. of the fluid had been injected, 4 mg. of arsenic would have been injected. It is hardly conceivable that all this arsenic would have remained in the body, because several washings of extremely dilute fluid are used

TABLE 2—CASES OF SO-CALLED HEMORRHAGIC ENCEPHALITIS

Case	Sex	Age Years	Survival After Onset of Symptoms Days	Mg. of Arsenic per 100 Gm.— Brain	Liver
8	M	40	1	0.18	Nil
9	F	32	4	0.12	0.125
10	F	36	5	0.20	Nil
11	M	32	Few	0.10	0.10
12	F	41	6	0.20	Nil
13	M	29	8	0.12	0.135

The average dilution of embalming fluid is twelve parts of water to one part of fluid. But even if all the arsenic were deposited in the body, it is altogether unreasonable to suppose that 37 per cent of the arsenic would remain in the brain, and this percentage would represent the smallest positive figure—namely, 0.1 mg. per hundred grams of brain tissue. In many of the significant cases (namely, Cases 1, 3, 5, 40, and 42) embalming was not done.

If the brains had not been embalmed before removal, formalin was injected into the circle of Willis in the laboratory. In any event, the brains were stored in a solution of 4 per cent formalin. Accordingly, chemical analysis of the formalin used in the laboratory was made and arsenic was not found. The fact that arsenic when found in the tissues could not have been the result of contamination by either the embalming fluids or the formalin used in preserving the tissues is amply demonstrated by the large series of control cases (14 to 43, inclusive) in most of which embalming had been performed before autopsy.

Although it is a matter of lesser importance, it was interesting to determine whether arsenic was leached out of the tissues by the formalin in which the organ was preserved. That this did occur is shown by a few cases in which the original arsenical content of unembalmed tissue was found to be several times that of the same tissue after prolonged fixation in formalin. In these cases arsenic could be recovered from the formalin provided that the brain was kept in an individual container.

However, in many instances an equilibrium was set up between the amount of arsenic in the brain and that in the fluid in which it was preserved. In these cases repeated determinations of arsenic over a period of five years yielded almost identical results (provided that the same region of the brain was used). The difference in results was usually less than 0.06 mg. per hundred grams of tissue, and the lower content of arsenic resulted from the more recent determination.

However, if a brain that has been kept in an

* Arsenic was found also in the gastric contents

changes in the bodies of the nerve cells. The vasomotor paralysis leads primarily to engorgement of the smaller vessels and to edema of the central nervous system. Subsequent fatty degeneration of the endothelium of these vessels leads to the formation of thrombi and perivascular changes—namely, necrosis, gliosis, and hemorrhages. Emboli, perhaps consisting of Voegtlin's protein-arsphenamine precipitate,⁸⁴ may play a role.

Finally, if the individual survives three or four days, mesodermal elements (at first polymorphonuclear cells) infiltrate the regions of perivascular necrosis. Later, the walls of the vessels become hyalinized, and those mesodermal elements associated with chronic inflammation (lymphocytes and plasma cells) appear in the form of perivascular cuffs—that is, an inflammatory reaction.

For many years neuropathologists attempted to draw a distinction between essential or primary inflammatory disease of the brain, on the one hand, and "inflammatory reactions" on the other. They felt that the first group of designations should be restricted "to inflammatory diseases of the brain of infectious origin, no matter whether or not the infectious agent is identified."⁸⁵ Although Jakob⁸⁶ stated that lymphocytic infiltration in cases of encephalomyelitis signifies the presence of bacterial infection and Pette⁸⁷ stated that it signified the presence of a virus infection, Spielmeyer⁸⁸ has clearly enunciated the nonspecificity of each of the components of the encephalitic reaction. He stated that,⁸⁹ if an injury induces a defensive reaction on the part of the living organism, the pathologic lesion in general is the same, regardless of the nature of the injurious agent, visible or invisible germs, toxic infectious injury, exogenous poison, or even endogenous, metabolic, or destructive processes. The same mechanism of defense is put into action in any case. Spielmeyer's views, now widely accepted, may have evolved from those of Oppenheim and Cassirer⁹⁰ who stated that,

by and large, all agents that can damage the organism either through intoxication or infection can lead to severe alterations in the brain itself by way of the blood stream. The hematogenous character of the lesion can be seen in the changes that begin in the neighborhood of the blood vessels, especially near the small vessels. Recently, Globus⁹¹ also pointed out the striking confluency of all the forms of encephalitis.

Before considering the question as to whether arsenic is the etiologic agent in any of our cases, it may be well to observe the effects that have resulted from the long-continued effect of other chemical substances. We now know that the encephalitic reactions are nonspecific and that typical inflammatory changes have been caused by the intracarotid injection of various agents.⁹² Similar lesions have resulted from the experimental introduction of certain substances such as trypan blue into the spinal fluid or cerebral tissue.⁹³ Inflammatory cells have been reported in chronic poisoning from lead,⁹⁴⁻⁹⁵ manganese,⁹⁶ cocaine,⁹⁷ cyanide,⁹⁸ carbon monoxide,⁹⁹ and mushrooms.⁹⁹

In judging whether perivascular infiltration may result from exogenous toxins, the element of time must be considered. At least a few days are required for the development of such infiltration. Even after long-continued exposure to a poison, one cannot expect to find encephalitis unless there had been clinical evidence that the brain had been affected. With these two factors, apparently dissonant neuropathologic reports may be harmonized. From the evidence presented it is clear that "chemical encephalitis" is not rare.

Material and Methods Used in the Present Study

General Plan—Three series of cases in which death was unquestionably attributable to arsenical poisoning were studied from the clinical, pathologic, and chemical points of view. Cases 1 to 4 (Table 1) represent instances in which a large dose of inorganic arsenic was ingested and in which death ensued within twenty-four hours. Cases 5, 6, and 7 (Table 1) represent instances in which death occurred within a period of a few days and in which significant amounts of arsenic were found in the viscera, even though arsenical poisoning had not been suspected clinically. Cases 8 to 13, inclusive (Table 2), represent instances of so-called hemorrhagic encephalitis in which appreciable amounts of arsenic were found in the brain. Cases 1 to 13, in-

* Numbers of cells in the spinal fluid are given per cubic millimeter. The significance of the other numbers follow: 0 indicates normal or absence of abnormality; 1, 2, 3, 4 indicate degree of pathologic alteration or of increase in number of cells.

forms (Cases 1 to 4) to the acute forms of hemorrhagic encephalopathy (Cases 8 to 13, Table 2) and the subacute and chronic forms (Cases 44 to 55, Tables 3 and 4). As would be expected, the liver contains much more arsenic than the brain in most acute cases. The findings in Case 3 are exceptional because of the relatively low concentration of arsenic in the liver. The actual amount of arsenic in the brain is consistent with that in the other cases (Table 1).

Cases of So-Called Hemorrhagic Encephalitis

The symptoms were typical and included headache, convulsions, coma, and focal signs. The pathologic findings were characteristic and included advanced cerebral edema, marked proliferation and acute swelling of oligodendroglia, and widespread hemorrhages. In all cases there were regions of necrosis and demyelination which Russell¹⁷ has emphasized. In 4 of the 6 cases there was the beginning of perivascular infiltration. In 3 cases (9, 11, and 13) there was equal concentration of arsenic in the brain and liver, but in 2 cases (8 and 12) there was much more arsenic in the brain than in the liver (Table 2).

Main Group of Controls

This series of cases (14 to 37) included many different types of encephalopathy from which only the syphilitic varieties were excluded. The patients ranged in age from less than 1

year to 60 years. There was some intracranial lesion in every case, and in many instances there was some other somatic disorder. Of the 24 brains there was no arsenic in 15 and from 0.02 to 0.05 mg per hundred grams of tissue in 9.

In Cases 31 and 32, lesions morphologically identical with those of our main series (Cases 44 to 55) were found. However, repeated examination of the brain revealed the absence of arsenic and apparently demonstrated that these morphologic changes are not specific, however, the arsenic may have been present formerly and may have been excreted before the patients died.

Special Group of Controls

Since it might be thought that the arsenical compounds circulating through the body might tend to be deposited in a locus minoris resistentiae, we sought a special group of control cases of known etiology which were to resemble the cases of encephalitis in duration, symptoms, and pathologic findings. Therefore, from 16 instances of fatal, malignant hypertension in which the brain was available for study,¹⁰⁴ we selected those 6 cases in which perivascular "cuffing" (the landmark of encephalitis) with lymphocytes and plasma cells was most marked. Small hemorrhages and multiple infarcts were present in each case. The cellular infiltration was generally from one to three cells deep and was found usually in regions of necrosis. Adjacent to the

TABLE 3—SUBACUTE ENCEPHALITIS WITH ARSENIC PRESENT IN BRAIN, CLINICAL AND CHEMICAL FEATURES

Case	Sex	Age, Years	Clinical Diagnosis	Survival After Onset of Cerebral Symptoms	Mg of Arsenic (per 100 Gm. Brain Liver)
44	M	36	Diffuse encephalomyelitis	5 wk	0.30

individual jar for some time and has been proved repeatedly to contain an appreciable amount of arsenic is then placed in a large formalin-filled crock with many other brains, most of the arsenic may then be leached out of the brain tissue. This observation was made repeatedly.

Accordingly, all of the determinations made on brain tissues and recorded in this study have been made either on fresh tissue that has not been stored in formalin at all or on tissue from brains that were stored in small individual containers.

That arsenic is not always distributed homogeneously throughout the substance of the brain was pointed out first by Osterberg and Kernohan,³¹ who found a greater concentration of arsenic in the white matter than in the gray matter of the brain in their 4 cases of pericapillary hemorrhage. Although in some cases of the present series, smaller amounts of arsenic were found in less severely damaged regions of the brain, if arsenic was present at all, it was always found in maximal concentration at the site of the greatest pathologic change. Whenever more than 0.1 mg of arsenic per hundred grams of brain tissue was found, there was profound histopathologic alteration.

The reliability of the method, apparatus, and reagents used is beyond question. They have been used in thousands of determinations in the routine work of the institution. Indeed, our own controls (Cases 14 to 43, inclusive) are evidence in themselves of the reliability of the test. The possibility of an infinitesimal amount of arsenic being present as a contaminant is admitted but does not come into consideration so far as the amounts that have been recorded are concerned. Indeed, anything less than 0.02 mg per hundred grams of tissue (corresponding to 0.001 mg of arsenic actually determined) was considered a negative observation. Our determinations are recorded in terms of elemental arsenic per weight of fresh or wet tissue.

Neuropathologic Methods—In each case many blocks of tissues were studied. In most instances, the tissue was embedded in paraffin, and hematoxylin-eosin stains were made first. The other staining methods used were the cresyl violet, Mallory's phosphotungstic acid hematoxylin, Weigert's stain for myelin sheaths, Cajal's gold chloride and sublimate, and the Hortega silver carbonate methods of impregnation. These methods have been described elsewhere.¹⁰¹

Acute Fatal Poisoning from Inorganic Arsenic (Cases 1 to 7)

Whenever the history was available the symptoms were typical of those of acute arsenical poisoning—vomiting, headache, diarrhea, and in 2 instances convulsions. In Cases 1 to 4, in which considerable amounts of arsenic were found in the stomach, death occurred within twenty-four hours. In these 4 peracute cases the most definite evidence of pathologic change in the brain was in the oligodendroglia which had become greatly swollen and had apparently multiplied. Also, proliferation of the microglia and cerebral edema were present. There were incipient nonspecific changes, chromatolysis or pyknosis, in the nerve cells. These changes are similar to those of "serous encephalitis" of Brown and Symmers¹⁰² and those of "acute toxic encephalitis" of Grinker and Stone.¹⁰³ The pathologic findings, therefore, must be considered as the nonspecific effect of a noxious agent which causes death very rapidly. A fully developed inflammatory reaction is not present.

In Cases 5, 6, and 7 the period of survival was from four to eight days. In addition to the observations made on the first group of cases, there were a few perivascular hemorrhages in Cases 5 and 6 and some perivascular cells similar to lymphocytes in Case 7.

These cells are mostly oligodendroglia. Cases 5, 6, and 7, therefore, represent the transitional stage from the peracute

poliomyelitis serum. Accordingly, the corresponding intramuscular injections of serum were given. Repeated examinations of the ocular fundi gave negative results. Occasionally, injection of a solution of salt and glucose intravenously was necessary to maintain a proper intake of fluid. Although nasal feeding was instituted, the patient became weaker rapidly. On November 20 the temperature, pulse rate, and respiratory rate increased and evidence of bronchopneumonia appeared. Death occurred on November 22.

Necropsy was performed two hours after death and before embalming was done. A bacteriologic culture of the heart's blood resulted in absence of growth. A specimen of the blood was sent to Dr. Thomas Rivers of the Rockefeller Institute in New York. He reported the absence of neutralizing antibodies for virus of lymphocytic choriomeningitis. Chemical examination of 100 Gm. of brain for the presence of lead was negative. However, 0.37 mg. of arsenic was found per hundred grams of brain tissue.

Examination of the viscera revealed bronchopneumonia, a chronic gastric ulcer, and chronic tuberculosis of the lymph nodes of the hilus, liver, and spleen.

Macroscopic examination of the central nervous system gave negative results. Microscopic study revealed severe encephalitis marked by a profound degree of perivascular infiltration with lymphocytes and plasma cells (Figs. 1 and 2). Chronic meningitis was also present (Table 4).

Summary of Clinical Observations—There were 9 male and 3 female patients in this group (Table 3). The ages ranged from 4 months to 65 years. The duration of life from the onset of cerebral symptoms varied from sixteen days to a few years. Although some evidence of diffuse cerebral disturbance was recognized in each case, evidence suggestive of specific cerebral localization was not found. Usually neurologic examination revealed drowsiness, generalized weakness, nystagmus when the patient attempted to look to either side, and Babinski responses which could be elicited on both sides. The diagnosis of arsenical poisoning was made in only 1 case (Case 49), and this was made by Dr. H. W. Woltman. The clinical course in these cases may be described as that of progressive diffuse cerebral failure. There was usually a history of fatigue and perhaps a mild headache for some weeks or months. Then the patient became bedridden and progressively weaker, slipped into coma, and died.

Although one could arbitrarily designate those cases with survival periods of a few weeks as "subacute" and the others as "chronic," there is no correspondingly sharp

demarcation in the alterations of the tissues as seen microscopically. This apparent discrepancy between clinical and pathologic observations is probably explained by the fact that diffuse minute cerebral lesions may be present for a long time before the patient is aware of any specific symptoms.

Summary of Chemical Observations—The brains contained from 0.10 to 0.83 mg. of arsenic per hundred grams of tissue (Table 3). These concentrations are of the same degree as those found in the more acute forms of fatal arsenical poisoning (Table 1) and also those found in cases of so-called hemorrhagic encephalitis due to arsphenamine (Table 2). A significant amount of arsenic was not found in the liver in any of these 12 cases. Unfortunately, in most instances the liver was not examined for arsenic until after the specimens had been preserved for some time in large crocks of formalin. However, in Case 49 the fresh, unembalmed liver was tested and it was in this case that the liver contained 2.0 mg. and the kidney 0.23 mg. per hundred grams, and that 1,443 cc. of urine contained both 0.04 mg. of lead and 2.3 mg. of arsenic.

Summary of Pathologic Observations—As indicated in Table 4, there was frequently an abnormally large number of cells in the spinal subarachnoid fluid. These cells usually were recorded as small lymphocytes, but the likelihood that some of them were plasma cells or oligodendroglia cannot be denied. The number of cells in the fluid was generally proportional to the number seen in the meninges at histologic examination. There were erythrocytes and occasional polymorphonuclear cells in the meninges of only the postoperative cases (Cases 47, 50, and 51).

Gross examination of the brain in these 12 cases revealed few noteworthy findings. In 5 cases there was slight atrophy of the cortex, in the same number there was granular ependyma, in 4 the brain was grossly normal, and in 1 case each, edema, congestion, and increased density of the white matter were present.

Chromatolysis of the nerve-cell bodies was generally present in moderate degree, but it is questionable whether these alterations signify antemortem or postmortem degenerative changes. Pyknosis was generally absent. Moderate degrees of satellitosis and neuronophagia were the rule. Proliferation and swelling of the astrocytes were found to a moderate degree in Case 45—an infant. Similar "progressive" changes in the astrocytes to a lesser degree were also present in

recent infarcts, polymorphonuclear cells were also included in these zones of infiltration

The age of the patients ranged from 22 to 56 years. Symptoms had been present from four to eight months before death. Less than 0.02 mg of arsenic per hundred grams of brain tissue was found in each instance.

It is clear that these cases represent instances of diffuse cerebral damage in which cerebral symptoms lasted over a period of months. The fact that arsenic was not found in the brain in a single instance is strong evidence against the hypothesis that arsenic is deposited in the brain in all cases of chronic cerebral damage. This view is substantiated by those other instances of long-standing cerebral disease which are included in the main group of controls (Cases 14-37).

Subacute Encephalitis Associated with Presence of Arsenic in the Brain (Cases 44 to 55)

Report of a Representative Case (Case 48)—A rancher, aged 57, registered on October 29, 1937. He complained of generalized weakness of one month's duration. His past history included tinnitus, vomiting, vertigo, and progressive deafness in the right ear. For four or five years the episodes of severe vertigo and vomiting had been progressive in severity and frequency. However, his general health was good until one month before registration. At that time he was chilled for several hours. He had generalized soreness of the muscles for seven to ten days and generalized weakness which gradually progressed to the point of making him bedridden. There was an occasional mild bifrontal headache. His spinal fluid, examined one week before registration, exhibited normal pressure and a positive Pandy test. The concentration of sugar was 15 mg per hundred cubic centimeters of spinal fluid and there were 40 cells per cubic millimeter. Of these, 75 per cent were reported as lymphocytes. A pellicle did not form in the spinal fluid, and the results on culturing the fluid and examining the smear were negative. The result of the colloidal gold test was 5555431000.

Examination revealed an apathetic individual who responded to questions with great effort. The pulse rate, temperature, and blood pressure were normal. Examination of the limbs and viscera gave negative results. The cranial nerves were normal except for nystagmus in both horizontal and vertical directions and bilateral nerve deafness, more severe on the right than on the left side. The speech was moderately slurred. There was generalized muscular weakness of moderate degree. The abdominal and tendon reflexes were all moderately increased. The sign of Babinski and its confirmatory signs were present on both sides. There was moderate in-

coordination of all four extremities and some difficulty with successive movements. The patient was unable to stand or walk. The Kernig and Lasègue signs were slightly positive.

Examination of the eyes revealed that the rotations of each eye were somewhat limited in each direction, perhaps attributable to poor cooperation. Examination of the ocular fundi gave negative results, and the retinal arteriolar diastolic pressure was normal.

The urine was normal. The concentration of hemoglobin was 15.7 Gm per hundred cubic centimeters of blood. Erythrocytes numbered 4,440,000 per cubic millimeter of blood and the leukocytes, 9,000 to 12,500. The polymorphonuclear neutrophilic leukocytes ranged between 83 and 96 per cent, and the blood smear was not abnormal. The Kline, Kahn, Hinton, and Kolmer tests on the blood serum all gave negative results. Agglutination tests of the blood gave negative results for *Brucella abortus* and for typhoid and paratyphoid. The concentration of blood urea was 48 mg per hundred cubic centimeters, of blood sugar, 97 mg per hundred cubic centimeters, and of blood chlorides, 566 mg per hundred cubic centimeters. The sedimentation rate was 10 mm per hour on one occasion and on a later occasion was 3 mm per hour. Roentgenograms of the thorax and head were normal. Examination of the spinal fluid on October 30 revealed a clear, colorless fluid under normal pressure. The Kolmer and Kline tests gave negative results, and the total protein measured 15 mg per hundred cubic centimeters of spinal fluid. There were 57 small lymphocytes, 2 polymorphonuclear cells, and a few erythrocytes per cubic millimeter of spinal fluid. The result of the gold sol reaction was 5552210000. On culturing the spinal fluid on brain broth and on blood agar, growth of organisms did not occur. A Gram stain of the spinal fluid revealed no organisms. The concentration of sugar was 54 mg per hundred cubic centimeters of spinal fluid, and the concentration of sugar was 716 mg per hundred cubic centimeters of chlorides.

The patient's course was marked by disturbances of consciousness—apathy, restlessness, and occasional disorientation. Involuntary deviations occurred. The pulse rate, temperature, and blood pressure remained normal for three weeks. Examination of the spinal fluid was repeated November 8, 1937. The fluid was clear and colorless and was under a pressure of 19 cm. of water. Response to jugular compression was normal. The results of the Kolmer and Kline tests were negative. The total protein was 75 mg per hundred cubic centimeters of spinal fluid. There were 39 small lymphocytes per cubic millimeter, but neither polymorphonuclear cells nor erythrocytes were present. The result of the gold sol reaction was 5555321000. The concentration of sugar in the spinal fluid was 55 mg per hundred cubic centimeters. Cutaneous tests revealed a strongly positive reaction to stock encephalitis serum and to Los Angeles

progressive course in these cases excludes the type of encephalitis seen in St. Louis in 1933, that in Australia in 1917 and 1918, and that of equine encephalomyelitis recently reported in humans.

All of the investigations for other well-recognized etiologic factors have proved fruitless. Many bacteriologic studies of blood, cerebrospinal fluid, and tissues in these cases have failed to yield a pathogenic organism.

We can now come to the question whether arsenic should be considered the main pathogenic agent in Cases 44 to 55. In the first place, there is no doubt that the amounts of arsenic found in the brains of these cases are abnormally large. This observation in itself does not imply that arsenic is the cause of the condition, for it is possible that the arsenic that most Americans ingest and that must circulate in the blood stream before being excreted might be deposited at a locus minoris resistentiae in greatest concentration. To consider this possibility, a special control group of cases was studied. These cases (38 to 43) resembled the cases of encephalitis in duration, symptoms, and pathologic findings but were attributable to a well-recognized cause—namely, malignant hypertension. The fact that an appreciable amount of arsenic was not found in the brain in a single instance is strong evidence against the likelihood that arsenic is deposited in all brains that have been diffusely damaged over a period of months. Similar evidence is adduced from a consideration of those other instances of cerebral disease of long standing in which arsenic was not found in the brain and which are included in the main control group of cases (14 to 37).

Recapitulation

Well-recognized chronic arsenical poisoning frequently is manifested by diffuse cerebral symptoms, fatigue, headache, vertigo, drowsiness, and impairment of mental activity. These are precisely the same symptoms from which the patients in this group (Cases 44 to 55) suffered and which constitute a syndrome that is summarized as "progressive diffuse cerebral failure."

The toxic effect of arsenic on the nervous system is not specific and is marked by alterations in the ganglion cells and by regions of perivascular necrosis. In subacute and chronic cases these regions of necrosis become filled with lymphocytes and plasma cells. The cases in this series exhibit such changes.

Finally, the actual concentrations of ar-

senic in the brain (that is, 0.1 mg. of arsenic or more per hundred grams of brain tissue) in these cases are abnormally large. They happen to be the same as those found in cases of acute arsenical poisoning due to either inorganic or organic compounds of arsenic and recorded both in the literature and in our own series of such cases.

Therefore, all the observations (clinical, pathologic, and chemical) concerning these 12 cases of subacute encephalomyelitis are consistent with the hypothesis that they represent instances of chronic arsenical poisoning. Further evidence for or against this hypothesis can be obtained by microscopic studies of brains in cases of recognized chronic arsenical poisoning and by the determination of the content of arsenic in the excreta and tissues, especially the hair, in other cases of subacute or chronic meningoencephalomyelitis.

FIG 1 Posterolateral quadrant of thoracic region of spinal cord. Several blood vessels are "cuffed" with cells (Case 52). Hematoxylin and eosin stain ($\times 22$)

FIG 2 Perivascular infiltration in the thalamus (Case 51). Hematoxylin and eosin stain ($\times 200$)

Cases 47, 48, 51, and 53. Generally there were marked diffuse proliferation and swelling of the oligodendroglia and slight similar changes of the microglia. These changes are not specific and occur in most of the brains obtained in cases in which coma or other evidence of diffuse cerebral impairment has occurred before death. There were focal collections of microglia and oligodendroglia only in Case 45. Since this brain is that of an infant, these circumscribed aggregations of cells must be considered normal features, possibly germinal centers, and not as evidence of inflammation.¹⁰⁵ In no case was there severe change in the walls of the vessel or in their lumens. Neither thrombosis nor embolism was observed. Slight proliferation of the intima was present in some cases.

Perivascular aggregation of mesodermal elements was present in all cases and was usually observable with even the low power of the microscope. The perivascular cells were very numerous (Figs 1 and 2) in all instances except Cases 44, 46, and 49. With the exception of these 3 cases, evidence of a widespread inflammatory reaction could be found in every part of the central nervous system from the frontal poles to the conus medullaris. The gray matter and white matter were equally affected. In the 3 exceptional cases there was a lesser degree of infiltration around the smaller blood vessels in various parts of the nervous system. Even in these cases there was no apparent site of election for the perivascular cells. Since polymorphonuclear cells were rarely found among the infiltrates, they are not listed in Table 4. Usually the perivascular cellular infiltrates

were more profuse in the cases of longer duration. However, neither the number nor the kind of cells was related to the amount of arsenic in the tissue.

In all cases there was interstitial cerebral edema of moderate degree. The clear spaces around the ganglion cells and the blood vessels, which are recorded in Table 4 as pericellular and perivascular edema, respectively, do not represent certain evidence of antemortem change. Stains for iron were made in each case and failed to reveal the presence of this substance in the microglia, the adventitial coats of the vessels, or anywhere else in the tissues. There were no areas of demyelination—perivascular, subependymal, or otherwise. In brief, the histopathologic changes were those of subacute or chronic disseminated meningoencephalomyelitis. It is now being accepted¹⁰⁶ that these cases include a heterogeneous group of conditions.

Etiologic Considerations—Evidence of syphilis was not obtained from the history in any of these cases (44 to 55). Serologic tests for syphilis were performed on the blood in each case and on the cerebrospinal fluid in all cases except 1 (Case 45). All these serologic tests yielded negative results. Evidence of syphilis was not found in any of the tissues of the body, although a complete necropsy was performed in each case.

All of the cases were terminated fatally between 1924 and 1937. In no instance did the symptoms begin at the time of the pandemics of influenza and encephalitis (1917 to 1920). Furthermore, there was neither clinical nor pathologic evidence of the chronic forms of epidemic encephalitis. The slowly

THE NERVE PATHWAYS AND CLINICAL FEATURES OF SHOULDER PAIN IN RELATION TO ANGINA PECTORIS

H R MILLER, M D , New York City

THAT pain in the region of the left shoulder may enter into the syndrome of angina pectoris has been recognized by many observers. Indeed, not alone the left shoulder but the right articulation, as well as other areas supplied by various components of the cervical plexus, are known sites of pain.

The problems evoked in connection with these atypical manifestations revolve about the following questions. Is this pain an example of referred anginal pain which, in this instance, strikes an atypical zone? Is this pain of local origin, i.e., confined to the shoulder or neighboring territory, and free of any anginal connotation? Finally, does this pain arise outside the cardiovascular apparatus and coexist in sufferers of anginal pain in whom multiple foci for pain are responsible for bizarre and confusing clinical problems? This communication attempts to answer these queries and to offer an explanation for the various types of shoulder pain connected with angina pectoris.

But first let us try to be clear on what is meant by the term angina pectoris. It connotes a clinical picture or syndrome associated, as a rule, with a lesion in a coronary vessel, the heart muscle, or aorta and accompanied, in most cases, by a prominent triad of reactions—namely, shock, mental anguish, and intense precordial or radiating pain. Other well-recognized clinical features are sudden change in blood pressure, apnea or dyspnea, exhaustion, prostration, abnormal sweating, localized constriction of blood vessels or muscles, etc.

This, however, is not the entire story, for we must include cases with clinical manifestations of angina pectoris (sometimes even ending in swift, unexpected death) in which no demonstrable somatic damage comes to light. For example, the triad and the other signs and symptoms just listed have been observed in noncardiac states like (1) esophageal herniation and (2) in the form of severe thoracicobrachial neuritis graphically portrayed by Lian¹⁰ and Boyer.² Pain simulating the anginal type, as well as a variety of autonomic manifestations, is en-

countered also in valvular disease, anemia, Grave's disease, toxic states, etc.

It would appear, therefore, that we may speak of angina pectoris as occurring with or without cardiovascular damage. The clinical state that accompanies noncardiac conditions and is indistinguishable from what we are accustomed to call angina pectoris may be just as alarming and dangerous. The essential point is that, apart from any question of somatic injury and the problems that arise from this, the clinical manifestations, at least of the attack, conform to a group of reactions referable to the autonomic nervous system. These reactions are set off and distributed in the sympathetic and parasympathetic divisions.

Associated or not, as the case may be, with somatic alteration of the heart, coronary vessels, or aorta, in a generic sense angina pectoris may be looked upon as an expression of an abnormal physiologic activity of the autonomic nervous system as a whole. This activity involves not only the peripheral autonomic pathways but the central nuclear elements in the neuraxis, chiefly of the brain stem but also of the cortex and spinal cord. Accordingly, we would do well to study more carefully the autonomic manifestations by which any form of angina pectoris is announced, not neglecting, of course, the import of sequelae which ensue from pathologic alteration in the cardiovascular apparatus when the latter is damaged.¹¹

It is important also to re-emphasize that pain need not be the sole or even the chief testimony of angina pectoris. Pain may be absent, dyspnea, strange anxiety, abnormal sweating, constricting manifestations, variations in blood pressure, etc., representing the telltale evidence of this disorder. However, when anginal pain is present, it may be analyzed according to rather well-established anatomic and physiologic criteria. Anginal pain, as well as other types of pain in relation to the shoulder region, a subject that forms the main theme of this communication, is a case in point and may be taken as an example of the factors concerned with the usual or atypical radiation of cardiac pain.

As a rule, anginal pain is characterized by a reflection into a well-defined dermatomic

A PRIME CONSIDERATION

A speaker who was presenting the gavel to the president of a southern state medical society remarked that he was in his prime, and he said it reminded him of the old gentleman who was to marry a young girl. The old black mammy in the family resented it and said

"There can't nothing good come out of that wedding. You is too old for that gal."

He said "Mammy, I am just in my prime!"

"Yes, that's true," she replied, "but when she gets in her prime, where is your prime going to be?"

ally The relationship of such accessory groups to the heart and aorta is depicted in Fig 1 The diffuse and multiple afferent connections between a viscus and many cord segments is accomplished by these accessory fibers in conjunction with the main and predominant group This arrangement of fibers is a fundamental anatomic endowment

On occasions, the role of the accessory groups takes on a special significance This comes to pass when the fundamental anatomic pattern of afferent fibers lacks a preponderance of entry into the cord or when, for any reason, this zone of concentration, "the bottle-neck" White¹⁵ (i e, the upper white rami in the case of the heart innervation), for example, is destroyed (as after surgical intervention or paravertebral alcohol block) and the burden of afferent conduction is thrown upon accessory groups of fibers

A similar but more restricted possibility for bringing into action an increased number of fibers holds also for the somatic neurons Normally the connections between a dermatome and the neuraxis do not exceed three, at most five, consecutive cord segments, but the range may be greater, never, however, attaining the wide-flung and multiple pattern characteristic of the afferent visceral system of fibers

The Function of Accessory Afferent Fibers in Referred Anginal Pain (1) *The accessory sympathetic (visceral) neurons*—The accessory fibers, in our opinion, may play a part in the transmission of anginal pain into the shoulder The evidence for this is derived, at least, from three sources First, there is the clinical experience already mentioned, wherein (as after paravertebral alcohol block or after surgical procedures carried out on the left sympathetic cardiac innervation) anginal pain recurs and is propagated by left upper cervical nerves, into hitherto untouched areas Second, according to Heinbecker,⁷ in the case of the heart, "afferent fibers traverse the superior cervical sympathetic ganglion to the sensory root of the fifth cranial nerve and to the dorsal roots of the upper three or four cervical nerves via the gray rami communicantes Similar fibers pass from the middle cervical sympathetic ganglion to the fourth and fifth cervical dorsal roots, and from the inferior cervical sympathetic ganglion to the sixth, seventh, and eighth cervical dorsal roots Likewise, the afferent fibers pass through the upper six or seven thoracic spinal roots via both white and gray rami communi-

FIG 1 (From Angina Pectoris by H. R. Miller, 1939, Williams & Wilkins Co Reprinted by permission of the publishers.) This is a schema of groups of afferent fibers capable of transmitting referred anginal pain. (1) Represents the usual, well-recognized, sinistral group entering the Th 1 to 4 cord segments through corresponding white rami, (1a) is a similar dextral group much less frequently involved. (2) Represents upper left cervical fibers going from upper cervical ganglia to corresponding cervical cord segments, (2a) similar dextral fibers (3) Represents lower thoracic fibers going from the lower thoracic ganglia to corresponding cord levels, (3a) dextral fibers (4) Represents the pathway of cardiac afferent fibers in the left vagus destined for the medulla, (4a) a similar pathway on the opposite right side (5) Represents the pathway of vagal cardiac afferent fibers which ends in the superior cervical sympathetic ganglion, (5a) a similar pathway on the opposite right side (6) Not included in the drawing is the posterior group of rami connecting the upper thoracic sympathetic chain to the cardio-aortic plexuses (7) Also not included are the sympathetic fibers from the vertebral plexus, entering the cervical plexus and sending communications to the ansa of Vieussens The vertebral plexus is generally not accepted as an afferent pathway for cardio-aortic pain.

cantes" Third, the studies of Schragar and Ivy,¹⁴ Davis and his co-workers,⁴ and especially of Ashkenaz¹ have demonstrated that a viscus, the gallbladder for instance, is connected to the neuraxis by afferent pathways far more numerous than we were formerly led to believe

territory innervated by the left upper four intercostal nerves, this reflection or radiation skirts but does not often include the left shoulder. As a consequence, in most instances the differential diagnosis between pain arising in or confined to the shoulder region and the precordial (anginal) pain transmitted by these upper intercostal nerves into the pectoral region and down the inner side of the left arm is not a difficult task. The anginal pain, however, that lashes the shoulder and adjacent areas is not always so easily recognized or so accurately interpreted. Boas and Levy,² Edeiken and Wolferth,⁵ Libman,¹¹ and others have described such occurrences. This type of pain is an illustration, we believe, of the manner in which *the shoulder region acts as a dermatome equivalent for the reception of anginal pain*. At first flush, such occurrences seem puzzling in their mechanism and, from a diagnostic point of view, frequently are baffling in their clinical guesses. However, a careful analysis of the visceral and somatic neurons called into action throws light on these problems.

I Mechanisms and Pathways

(a) *The Single Nervous Pathway for Shoulder Pain*—The common variety of shoulder pain (and this includes pain from the bursa, muscles, bone, etc., also from the cervical or brachial plexuses) has but one pathway for its transmission—by somatic neurons. The registration of the pain is accomplished without the intervention of sympathetic fibers. The pain felt in this region has its genesis here. No mediation comes into play. This, therefore, is not referred pain. Moreover, the upper cervical nerves (C 4, 5, and 6) which carry sensory impulses from the shoulder enter the cord, in the majority of instances, well above those levels (Th 1 to 4) normally concerned with the mediation of referred cardio-aortic (anginal) pain.

(b) *The Dual System of Neurons in Referred Anginal Pain*—Two independent nerve pathways participate in the propagation of referred anginal pain. Impulses of pain, for example, originating in the heart, coronary vessels, or aorta are transmitted into the upper left thoracic segments of the spinal cord (Th 1 to 4) by afferent sympathetic visceral neurons. At these levels afferent somatic nerves (the upper intercostals) are brought into action, and these, together with the visceral fibers, function to refer pain into complementary related dermatomes. The dermatomes comprise the left infraclavicular

or pectoral region and the inner aspect of the left arm and forearm down to the tip of the small finger and the ulnar side of the fourth finger. The mediation of the reference of this pain, it is generally held, takes place in the substantia gelatinosa of the cord, but there is reason for believing that mediation is not always intraspinal and that it may take place, for example, in the dorsal roots.¹² At any rate, pain is engendered deep in the chest and reflected into a surface (dermatome) area.

(c) *The Afferent Conduction System in Referred Pain*—To understand referred anginal pain into the shoulder we must understand the afferent conduction system that connects viscera and dermatomes to the neuraxis and have some realization of the likelihood of anatomic variation that exists with regard to the afferent sympathetic and afferent somatic components of this system.

Each organ possesses a system of centripetal (afferent) sympathetic fibers which go to a specific number of dorsal roots and thence, it is believed, to the substantia gelatinosa in the cord. In most individuals these fibers converge predominantly upon a limited number of dorsal roots at a particular level of the cord, for instance, in the case of the heart the preponderance of convergence and entry is at the levels of Th 1 to 4 and on the left side, in the case of the gallbladder the levels are approximately Th 8, 9, and maybe 7 according to Head,⁶ Th 9 and 10 according to Kappis⁷ and Lâwen,⁹ and on the right side. This rather sharply defined concentration of fibers accounts for the particularity with which each organ, be it the heart or the gallbladder, etc., announces visceral pain into related dermatome areas.

The Anatomic Arrangement of Accessory Afferent Fibers—Although the bulk of afferent visceral fibers from an organ commonly enters the cord as a main group, a considerable number of these fibers reaches the cord at many other levels. Such fibers outside the zone of concentration, in most cases either too few or too diffuse to carry any appreciable quantity of sensory impulses of pain, are, nevertheless, accessory fiber groups and, what is more to the point, are capable of conveying visceral sensations into the cerebrospinal system. The existence of these groups, therefore, enlarges the potentiality of any viscus for bringing into action many cord segments otherwise involved passively or not at all. In this way the entire thoracic and even lumbar levels may participate, even bilaterally.

tion, or in the deltoid (C 5 and 6) or trapezius (C 3 and 4) muscles *

Often the anginal pain in the shoulder region is excruciating, limited to the shoulder itself, deep in the joint, or is situated superficially, spreading perhaps into supraclavicular and pectoral districts through lower cervical nerves. A point of interest is the occasional localization of pain posteriorly, for example, in the subscapular region. This is in contrast to the conspicuous absence of pain in the posterior chest wall in most cases of anginal radiation. After the sharp sting subsides, shoulder pain is known to linger as a dull ache. It is set off by movements in or near the joint, by pressure or the weight of clothing or bed clothes, or even by changes in meteorologic conditions. With respect to provocation, periodicity, intensity, duration, and spread, anginal pain at the shoulder differs little, if at all, from pain projected into other surface regions, and the shoulder, like other surface regions, may remain the sole outpost feeling pain, sometimes long after the precordial features have subsided. Whereas the localization of anginal pain into a shoulder is uncommon, all the other accompanying features of a paroxysmal episode of angina pectoris (coronary or noncoronary) may be typical.

(b) *Nonanginous Pain at the Shoulder Region Simulating Anginal Pain*—Many, if not most, of the nonanginous types of pain in this area are readily distinguished from anginal pain referred into this district. These types, in contrast to the anginal variety, are practically always more extensive. The pain overlaps the areas supplied by the musculocutaneous nerve (C 5, 6, and often 4) or the radial, musculospiral nerve (C 5, 6, 7, and 8, Th 1) or the median nerve (C 5, 6, 7, and 8, Th 1) and also the ulnar nerve (C 8, Th 1, and often C 7). In other respects, too, pain of this category is unlike the anginal in that it is diffuse not radicular, in that the posterior as well as the anterior chest wall feel pain, and in that features that accompany angina pectoris are usually absent.

The painful disorders at and near the joint are variable and too numerous to list here. Some are stubborn, others yield promptly to mechanical manipulation. Still other types of shoulder pain are due to destructive or deforming processes and are hardly amenable to simple methods of therapy. Limitation of

FIG 3 (From *Angina Pectoris* by H. R. Miller, 1939, Williams & Wilkins Co. Reprinted by permission of the publishers.) The routes for referred anginal pain to the shoulder. The afferent somatic neurons from the shoulder may enter the spinal cord by accessory fibers as low as the first or even second thoracic levels, a region that receives cardiac afferent impulses. Anginal pain could thus be referred through the lowermost (accessory) somatic neurons into the shoulder.

motions at the joint itself and localized points of articular tenderness aggravated by direct pressure or by passive movements are almost pathognomonic signs of local disease. A most frequent cause of pain in this locality, aside from arthritic conditions in general, are affections of the brachial or cervical plexuses, and those on the left side sometimes are apt to simulate anginal pain. An interesting and fortunately rare type is the thoracobrahial neuralgia described by Lian¹⁰ and also by his pupil, Boyer.¹¹ This is a severe sinistral neuralgia with intense pain into the precordium, the localization, the character of the pain, and the features of shock and mental apprehension which may accompany the pain conspire to make this picture strangely like a paroxysm of angina pectoris.

As a rule, however, brachial or upper cervical neuritis, a fairly common disorder, is sharp and abrupt in its onset, and its intense pain is well localized. The muscles supplied by the affected nerves may develop paralysis and later atrophy, and trophic alterations in the skin are not rare. The neuritis, as a rule, lasts weeks or months, disappears gradu-

* It is important to exclude pericardial and diaphragmatic pleural pain transmitted into the trapezius muscles by way of the phrenic nerve into C 4 and 5 cord levels.¹²

FIG 2 (From *Angina Pectoris* by H. R. Miller, 1939, Williams & Wilkins Co. Reprinted by permission of the publishers.) The routes for referred anginal pain to the shoulder. The fourth, fifth, and sixth cervical nerves connect the shoulder to corresponding cervical segments of the spinal cord. Visceral afferent fibers from the cardiac plexus reach the upper thoracic segments, Th 1 to 4, of the cord by means of corresponding upper thoracic white rami. In this drawing a group of cervical rami is portrayed that would be capable of carrying afferent impulses from the heart into those cervical cord segments that receive afferent neurons from the shoulder. Anginal pain could thus be referred into the shoulder.

Fig 2 illustrates the pathway of accessory afferent sympathetic fibers in the upper cervical region. Such fibers, in which in all probability sensory impulses are able to travel, Heinbecker,⁷ may well carry painful impulses from the cardiac plexuses into those cervical segments of the cord linked to the shoulder by the fourth, fifth, and sixth cervical nerves. These cervical segments could then serve as an intraspinal zone for the mediation and reference of anginal pain between heart and shoulder region.

(2) *The accessory somatic neurons*—In an analogous way (Fig 3) accessory afferent somatic fibers may exist in the lower cervical nerves and gain an entry into the segmental levels of C 8, Th 1 and 2, these are segments, as we have already observed, which can receive cardio-aortic impulses of pain. By these fibers, then, the shoulder could be brought into relation with a common intraspinal zone for the mediation of anginal pain, the shoulder serving as an additional district of reference.¹⁸

The multiplicity and wide dispersion of afferent visceral and somatic neurons and their potentiality of overlapping in zones of the cord other than those usually restricted to each organ and its complementary dermatomes make it possible to comprehend by what nerve pathways pain from a viscus can be projected into dermatomes (or into distant organs) otherwise unrelated. Furthermore, by virtue of this overlapping of both sets of accessory fibers, pain may travel in either direction, i.e., not only from a viscus to dermatomes but vice versa, in a reverse direction. This bidirectional conduction gives us a basis for comprehending the routes occasionally followed in the bizarre, reversed transmission of pain from a dermatomic area (shoulder or brachial plexus, for instance) into the precordium (see later).

II The Differential Clinical Diagnosis of Shoulder Pain

(a) *Anginal Pain Referred into the Shoulder District (Left)*—This type of pain is referred to the shoulder very probably as a consequence of the summated effect of two streams of impulses which reach a common area in the cord. The effect of (a) impulses derived from the shoulder and delivered to this common area by somatic fibers is combined with (b) the effect of impulses engendered in the cardio-aortic apparatus and transmitted by cardio-aortic visceral neurons to the same zone in the cord.

Clinically, it is sometimes possible to reduce the total quantity of impulses received in the cord by a variety of procedures. One of these is to press very hard on the brachial plexus as recommended by Libman.¹² The flow of afferent impulses in the plexus traveling toward the cord will be decreased and, thus, also the total number of impulses prerequisite for the induction of referred anginal pain. The same principle obtains in relieving referred anginal pain as when a local anesthetic is applied to a related dermatomic surface.

Generally speaking, referred anginal pain into the shoulder exhibits a radicular nature characteristic of the more common distributions. The reference is not diffuse but patchy and orderly, covering contiguous areas, occasionally, however, as is also the case with common radiations, the pain in the shoulder remains registered, for example, in one small area, i.e., over the subacromial bursa or in the biceps muscle or at its inser-

as a prelude to treatment. One part of such system should always be a careful functional test of the structures from which the pain might arise—that is, a careful palpation, manipulation of joints, etc. Another is the use of novocain block in nerve trunks, plexuses, nerve roots, or by means of spinal anesthesia. Dr. Miller has mentioned that using novocain in the area of reference may lead to relief, and I can easily imagine that one could be misled by this into supposing that the pain had a local origin. I should like to ask Dr. Miller whether some functional test of the heart muscle—say a standardized exercise or injection of adrenalin—may be relied upon to elicit pain in the shoulder of cardiac origin and might therefore be of diagnostic aid.

I should also like to ask Dr. Miller whether his observations have a bearing on the surgical treatment of cardiac pain.

This paper seems to be an outstanding example of the manner in which urgent clinical problems may impel an internist to make physiologic observations overlooked by the pure physiologist.

Dr. Tasker Howard, *Brooklyn*—A stiff and painful left shoulder in a patient with coronary occlusion or angina pectoris is a common and often a troublesome complication. It is much more common than the occurrence of immediate pain in or about the shoulder joint during an attack of angina or during the initial pain of coronary occlusion. A patient will have no pain at all in the shoulder during severe attacks of cardiac pain, which may be referred down the inner side of the arm, and yet later develop a very lame shoulder joint. With this lame joint, if untreated, he may develop severe aching in the joint, in the neck, and down the outer aspect of the arm or the whole arm. If this is a matter related to the influence of the reflex arc originating in the heart, why does he not have the aching at the site of the original referred pain instead of in an area rarely so affected? Dr. Miller has told us that the usual area of referred pain is in the left pectoral region and down the inner side of the left arm. Pre-existing pathology almost never exists in this zone. On the other hand, low-grade inflammation is common in and about shoulder joints,

particularly in the bursae. Dr. Libman¹ believes that it is more common in patients with coronary disease, since they both so often depend upon an underlying "gouty diathesis." These affected tissues about the shoulder, while lying outside the main current of reflex influences—that is, the upper four dorsal segments—may well fall within the scope of the accessory paths described by Dr. Miller.

If pain is initiated in this manner, the patient is inclined to keep the joint very quiet, thus putting into effect the mechanism described by King and Holmes² whereby the inactivity leads to loss of tone in the supporting muscles and ligaments with consequent relaxation of the capsule and increased vulnerability. The impaired circulation and lowered metabolic activity adds to the local difficulty. Tending to substantiate this view of the situation is the fact that physical therapy and particularly active movements of the shoulder joint are the most potent measures for its relief. It should be treated early. On the first appearance of shoulder lameness, the patient should be instructed to flex the arm with the palm at the front of the shoulder to reduce the load and abduct and rotate the shoulder joint repeatedly several times a day. It is a light exercise but very effective in clearing up this painful complication, particularly if it is instituted early.

Sir James McKenzie long ago pointed out segmental zones of hyperesthesia in patients with angina pectoris. These quite regularly corresponded to the segments Dr. Miller has designated as the usual pathway of referred cardiac pain and seldom included the region of the shoulder joint. The reflex influence alone therefore could scarcely account for the frequency of this phenomenon. That it has something to do with it is implied by the fact that the right shoulder is not affected unless there is some right-sided cardiac pain. All of this tends to substantiate Dr. Miller's conclusion that local pathology, usually pre-existing, plus reflex pain impulses to the shoulder joint or its immediate neighborhood, is most often responsible for the stiff and painful shoulder of angina pectoris and cardiac infarction.

ERASING THE STIGMA OF BEDLAM

An association organized by recovered psychiatric patients to fight the stigma attached to mental illness is doing much to restore such persons to a normal place in the social and business world, Pauline Rosenberg, Chicago, reports in *Hygeia, The Health Magazine* for November.

Founded in 1937, the organization is called "Recovery, the Association of Former Patients

of the Illinois Psychiatric Institute." Today it comprises more than 150 former patients and 600 relatives and friends who are associate members. Since its organization there has been a steady decrease in the percentage of relapses at the Institute, a large number of which are due to discrimination, distrust, fear, and suspicion that patients encounter on their return to the social and economic world.

ally, but is likely to leave weakness in its wake for many weeks. Parasthesias are frequent with the intense pain, and Horner's syndrome is a complication of some forms of cervical neuritis. Gout, diabetes, anemias, leukemias, poisons like alcohol, metals, and vitamin deficiencies are etiologic factors in the production of brachial as well as cervical neuritis. Infections like influenza, for instance, induce neuritis and local mechanical causes are numerous, e.g., a cervical rib or pressure from fractures, dislocations, tumors, etc., of the bone, or aneurism of nearby vessels, disease of the cord itself or its surrounding bony structures. In all these instances the resultant neuralgia may be homolateral and the distribution of pain will spread along the nerve pathways of the particular portion of brachial or cervical plexus involved.

(c) *Pain in the Shoulder Region Induced by Local Disease in Anginal Sufferers Who Also Refer Anginal Pain into the Shoulder*—Painful impulses simultaneously from two foci, i.e., at the shoulder and in the chest, combine to produce confusing clinical pictures. Thus, an anginal victim with a local lesion in or near his left shoulder may set up converging streams of sensory impulses traveling toward the neuraxis, and, if these impulses reach common cord levels connected to the heart and aorta and to the left shoulder, pain clinically may be bidirectional, i.e., projected in either direction from one focal area into the other. The manifold lesions that may strike the shoulder independent of a cardiovascular state and instigate bidirectional transmission of pain from the precordium to the shoulder or in a reverse direction need not be enumerated at this time. Careful analysis generally will yield the clue as to which focus is the chief offender with respect to initiating pain in its own vicinity and in the other focal zone.

An illustration of this bidirectional phenomenon is exemplified in the occurrence of precordial pain associated with pain from a bursitis or any similar localized lesion in or near the left shoulder in a subject suffering from coronary artery disease, for instance. The cardiovascular apparatus may be responsible for referred pain into the shoulder and conversely the localized lesion at the shoulder may precipitate precordial pain.

Summary

1 Shoulder pain per se has its own somatic pathway. This is not an example of referred pain.

2 Anginal pain into the shoulder is an uncommon instance of referred anginal pain.

3 The mediation of this uncommon type of referred pain is accomplished (a) at the usual intraspinal segments, Th 1 to 4, through the intervention of somatic accessory afferent neurons from the shoulder traveling in the lower cervical plexus or in the upper intercostal nerves, or (b) the mediation takes place in cervical levels of the cord where the usual somatic nerves from the shoulder enter into cooperation with the action of accessory (cervical) afferent visceral neurons.

4 The more precise clinical differential diagnosis and management of the anginal and nonanginal types of shoulder pain rest upon a sound understanding of the nerve pathways involved.

Discussion

Dr Tracy J. Putnam, *New York City*—The subject of pain in and about the shoulder is an important and baffling one, and the suggestion Dr. Miller has made in regard to it appears to me to be original and stimulating. It is wholly reasonable to suppose that there may be an overflow of the pain from the angina into the upper cervical segments, and, as Dr. Miller has indicated, we may even find evidence for anatomic pathways. In a rather limited experience, I do not recall seeing any cases in which shoulder pain appeared to arise from the myocardium, but this may well have been because I was not awake to the possibility that it might occur.

In dealing with pain of obscure origin, it is, it seems to me, important to attempt to work out a systematic plan of differential diagnosis.

longed The audiogram shows a loss for the perception of low frequencies and a relatively good bone conduction for low and high tones The fitting of this type may be successful with a bone-conduction device However, if the so-called air conduction, a receiver attached to a mold fitted in the ear canal, gives as good results as the bone and if there are no contraindications to the use of the air receiver, air conduction is preferable The air receiver gives a much wider frequency range, and speech sounds more natural In a chronic suppurative ear or one in which there is a perforation in the drum head and where the patient is subject to recurring discharge, the bone conduction receiver is preferable A receiver fitted to a mold that has been made for the individual patient gives not only good air conduction but bone conduction at the same time, the vibrations striking the bony walls of the ear Radio-tube amplification is generally to be preferred to the carbon microphone instrument as it has been developed to date Class I is the only group with impaired hearing that can use a carbon microphone instrument very well, although we prefer the radio-tube instrument in most cases For all other kinds of hearing impairment the radio-tube amplifier is best To this first class belong many cases of clinical otosclerosis

The Pros and Cons of the Fenestration Operation

There has been much discussion lately on the fenestration operation to improve the hearing of patients with otosclerosis Land-say⁴ stated in a discussion on Lempert's operation "The most favorable condition for operation is fixation or ankylosis of the stapes with a free round window niche and membrane and good bone conduction. This is one condition also in which best results are attained with bone conduction hearing aids" To us, the opposite also seems to be true Where a bone-conduction hearing aid will not improve hearing, the functional results of the operation will be doubtful These statements are backed by experiments on bone conduction by Békésy⁵ Let us analyze briefly the pros and cons of the fenestration operation *versus* the hearing aid for the same disability

The advantages of the fenestration operation are (1) that sound perception after operating is more natural and (2) that the patient has not the bother of a hearing aid The disadvantages are (1) that no surgeon can promise the patient that the functional

result of the operation will be a lasting one, the result depending upon the reparative reaction on the bone, which no one can foretell (2) The operation constitutes an artificial communication between the middle-ear structures and the intralabyrinth and intracranial structures, leaving a pathway from the middle ear to the brain Although there seems to be no danger of an intracranial complication immediately after it, the prognosis of an incidental infection, after several months, of the tissues surrounding the fistula may be similar to that of an otitis with labyrinth fistula (3) The operation alters the biologic condition of the labyrinth capsule by removing tissue and by the procedure of the plastic This last statement is made with reference to Neumann's⁶ study on late changes of the bone surrounding the cavities in the radical mastoid operation He claims that the progressive loss of hearing in ears having the radical operation is due to otostatic changes taking place in the bony labyrinth We do not know of any study having been made on late changes of the bone after the fistulation operation, nevertheless we are inclined to believe that the new condition in which the bone finds itself may alter the present otosclerotic pathology for the worse In other words, if an operation becomes functionally unsuccessful after a period of time, the second disadvantage disappears by closure of the fistula but the third one remains, i e, the new condition in which the labyrinth capsule finds itself after operation If, after an unsuccessful operation, the patient has to wear a hearing aid, his condition is worse than if he had not been operated upon

The disadvantages of the hearing aid are (1) that sound will not be received as naturally as after a successful fistulation operation, and (2) that the patient has to wear a more or less conspicuous instrument The advantages are (1) that the patient will hear with the aid as long as the batteries and the mechanism of the instrument are good, (2) no operative measures are necessary, and more important still (3) the psychologic reaction of the patient on the eventual failure of the operation does not have to be overcome Weighing the pros and cons of the said problem we are in favor of the hearing aid

We have not read, unfortunately, of cases where the results gained with a properly fitted hearing aid have been compared with the results of the fistulation operation on the same patient. We would suggest that any patient to be subjected to the operation

SOME PROBLEMS INVOLVED IN THE FITTING OF HEARING AIDS

THOMAS H. HALSTED, M D, F A C S, * and FREDERICK M. GROSSMAN, M D, New York City

THE number of persons in the United States who are hard of hearing or deafened is estimated by Dr. Gordon Berry¹ to be six to eight millions. The late Dr. Austen B. Hayden estimated that there are five million people in the United States who require an instrument to give them the necessary hearing. This estimate may be high, but it certainly shows the hearing-aid problem to be a major one.

Kerridge² says "Medical men dealing with deaf people have been hampered through lack of knowledge of acoustics and of facilities for carrying out a difficult research, necessitating an elaborate technique not used in other branches of medicine. Physicists and instrument makers interested in this subject have been handicapped on their part by insufficient information on the physiology and pathology of the ear." It is not within the teaching of medicine that acoustics belong.

A frequent reason for the otologists' distrust of hearing aids is that the whole subject has been in the hands of manufacturers, and patients recommended by the otologists to purchase an instrument found too often that they were not fitted properly. Thus the instrument was thrown aside to the disappointment of the patient and with a loss of prestige to the recommending otologist. It is not uncommon to see patients who have bought five or six hearing aids, all of which were discarded after a few weeks or months because they were not properly fitted or because the patient could not hear at all, lip reading being the only means of helping him. Of course he should never have been sold an instrument in the first place.

Acousticians and engineers discovered the basic principles of transmission of sound and its reaction on normal ears. These principles are only applicable, to a certain extent, to deafened ears, and experiments in sound transmission with impaired ears are scarce. The relationship of intensity and frequency to pitch, loudness, and perception of quality in ears with impaired hearing is not applicable to ears with normal hearing. A review of the

literature dealing with experiments on defective hearing apparatus by modern means of experimentation shows very little on the subject. Kerridge² says further "Until the optimum compensation for defective hearing has been worked out scientifically in a reasonable number of cases of different types and degrees, it will be impossible to forecast what amount of approximation to the ideal would suffice for most practical purposes."

Watson and Knudsen,³ physicists, have made thorough tests with defective ears and have drawn certain conclusions from them. Taking the intelligibility of test words as a criterion, they tested the impaired ears with a series of differently adjusted amplifiers built to compensate their specific loss. They found among other important data that a hearing aid chosen by the deafened is not necessarily the best fitting one. "Until the patient becomes accommodated to the proper amplification, he almost invariably chooses as 'best' a 'peaked' amplifier or one which accentuates most of the frequencies he already hears best, and paradoxically he frequently says he hears poorly with an amplifier with which he actually hears best." This statement, based on experimentation, goes to show that the method of fitting a hearing aid by choice alone must be revised and more objective methods used in routine tests by a person who is trained in the new science of fitting hearing aids. Unfortunately, in many experiments detailed clinical conditions of the ears tested have not been stated. We feel that the pathophysiologic condition of impaired ears is of fundamental importance, and we classify hearing impairment into *four broad classes* with respect to the fitting. In practice there is seldom found a pure uncomplicated case, but in the majority of cases one of the four classes predominates.

Class I is the middle-ear conduction or middle-ear impedance hearing impairment. This is caused by impedance and distortion of sound waves by parts of the external or middle ear, including the foot plate of the stapes, and by no pathologic change beyond it. It is characterized by well-known symptoms—Weber lateralized to the more affected side, Rinne negative, bone conduction pro-

* Emeritus professor of otolaryngology, Syracuse University College of Medicine.

examined later, it is merely a suggestion of further differential diagnosis in hearing impairment

The best hearing aid for this second class of hearing impairment is a strong undistorted tube amplification with a receiver fixed to an individual mold

The two other classes are also known as perceptive deafness. Their symptoms are different from each other, and they have to be fitted accordingly by different, adjusted hearing aids. Crowe, Polvogt, and Guild,¹² have pointed out important differences between gradual high-tone deafness and abrupt high-tone deafness. They link the latter with a degeneration of the organ of Corti, known as boilermaker's deafness, and the former with a degeneration of the nerve tissue

Class III or abrupt high-tone deafness has as its principal symptoms the loud voice of the patient, men's speech better heard than women's, lateralization of the Weber test to the better side, Rinne positive, and bone conduction shortened. The audiogram shows an abrupt perception loss for high frequencies. It is assumed that the organ of Corti transforms the physical sound impulses into proper physiologic nerve impulses, therefore, when the organ of Corti is degenerated, this transformation cannot take place. A patient with this condition ordinarily asks for an instrument when the condition is developed to a point where the perception of higher frequencies necessary to the discrimination of speech is insufficient. By strong amplification of the higher frequencies the perception of them can be slightly improved, but this slight improvement gives an inordinate amount of intelligibility out of all proportion to this little improvement of perception in the high frequencies. The compensation derived from a hearing aid depends entirely upon the stage of the condition. A loss of perception beginning around the 2,000 cycle may be compensated fairly well, but a loss beginning around the 1,000 cycle makes the fitting difficult. The amplifier of the instrument should accentuate the high frequencies, and a crystal receiver fitted to an individual mold should be used. We would suggest for further development an even stronger suppression of the low frequencies in order to prevent them from masking the remaining high ones

Class IV of hearing impairment is interesting because of its close relationship to recent research of the physiology and pathology of

the nervus cochlearis, the auditory nerve. It shows symptoms that can be due to an insufficiency of nerve tissue which conducts impulses from the organ of Corti to the higher centers. A short review of the results of neuro-otologic research will illustrate this relationship. It is assumed that the acoustic nerve follows the same principle in carrying impulses as other nerves. The function is characterized by the "all or none" law, which means that after every single transported impulse in a nerve fiber, a refractory period prevents the fiber from carrying another impulse in the interval. It is further assumed that the interval is the one thousandth of a second, in other words, a single nerve fiber of the acoustic nerve can carry 1,000 impulses per second. Again, the number of impulses to be carried by the nerve depends on the frequencies and intensities of the acoustic impulse. Every cycle is represented by an impulse—therefore, the higher the frequency, the more impulses. If a tone has more than 1,000 cycles, which is called the critical frequency, a single nerve fiber is not enough to carry it and a second fiber must help, it is called alteration. Higher tones must be carried by still more fibers, this is called rotation.

Furthermore, it is very probable that the number of active fibers increases in proportion to the intensity of the stimulating tone. It is clear from the above that tones of high frequency and great intensity constitute a higher duty for the nerve. It is important to realize that a certain number of nerve fibers is linked to a corresponding area of the organ of Corti. The nervus cochlearis or the acoustic nerve may be compared to a rope of nerve fibers emerging from a corresponding area of the organ of Corti. This means that impulses coming from low frequencies and high frequencies, respectively, will be carried by their corresponding nerve fibers. This discrimination has been traced in animals into the higher nerve centers. If the number of impulses to be carried is very high—as, for instance, stimulation by a loud noise—the transportation of these impulses needs a great number of nerve fibers. If the number of elements available is smaller than the need, as in the case of a partly degenerated nerve, the nerve becomes physiologically insufficient. What is the clinical picture of a patient suffering from insufficiency of the acoustic nerve? His voice is rather low, if asked whether he is hard of hearing, he will usually deny it, specifying his difficulty as a distortion of sound rather than a lack of

should be first fitted with a hearing aid and the actual gain in hearing established with the aid and later compared with the gain obtained through the operation

Class II may be called the inner ear conduction or impedance hearing impairment. I is caused by pathology of the hydraulic system of the cochlea. If, for instance, the membrane occluding the round window is rigid, the basilar membrane cannot move normally, although sound reaches the inner ear without any pathologic impedance of structures peripheral to it. In this condition the movement of the basilar membrane will be impaired no matter whether the sound is conducted to the inner ear by air or by bone. There may not be any pathology of the perceptive apparatus proper, but hearing will be impaired because of mechanical obstacles in the hydraulic mechanism of the inner ear. Although there are no routine tests to make differential diagnosis with respect to changes of the round window membrane, there are other changes in the hydraulic system which are accessible by proper testing approach.

Crowe⁷ observed in many cases of impairment of hearing in Ménière's symptom complex the interesting fact that hearing fluctuates markedly in this condition. Hallpike and Cairns⁸ link Ménière's symptom complex to a hydropic change of the ductus cochlearis based upon their histologic studies. Adams⁹ calls this condition "glaucoma auris." Shambough, Jr.,¹⁰ made a thorough study of diplacusis in describing 42 cases of different clinical conditions having this symptom. He could find diplacusis in Ménière's symptom complex, otosclerosis, otitis media, and many other conditions. He links this symptom also to hydropic changes of the endolymph and gives, in this same paper, a detailed description of the symptoms connected with the said changes. Incidentally Békésy¹¹ found the experimental explanation for Shambough's assumption. He studied the mechanics of sound transmission in the hydraulic system of the inner ear. He made a model of the cochlea, replacing the bony parts with metal and the basilar membrane with a thin rubber membrane, and observed through a glass window what happened inside the model when sound impulses moved a piston, replacing the foot plate of the stapes. He observed that two eddies developed in the scala vestibuli and tympani, respectively, pressing toward the basilar membrane. They changed their position according to the frequency with reference to the distance from the artificial

stapes. High frequencies produced eddies near the stapes and low frequencies produced eddies distant from it. He assumes that the basilar membrane includes physically the ductus cochlearis. Referring to the model, where not only the basilar membrane but also the ductus cochlearis and Reissner's membrane have been imitated, the author claims: "It can be demonstrated that the form of vibration of the basilar membrane is the same as before." He states furthermore that a change in the elasticity of the rubber membrane replacing the basilar membrane in the model is followed by a shift of the pairs of eddies toward the piston. He claims that "according to the frequency of the stapes, the eddy is located at a different position of the membrane. At low frequencies the eddy is near the helicotrema and at high frequencies near the stapes. With constant frequency of the impulse anticipated, the eddy is nearer the stapes if a thicker membrane rather than if a thinner one is used. Because of the great amount of absorption of water by the rubber membrane, the elasticity of it decreases with time. In this case also the eddy moves toward the starrup bones." If Shambough could demonstrate that the pitch, in almost all cases, was higher in the more affected ear, he would prove the clinical observation for Békésy's experiments.

The striking correspondence between the results of Békésy's experiments and Shambough's clinical observations testifies to the validity of both assumptions. We could find in cases where we assume pathology of the hydraulic system that very loud tones of the audiometer do not produce any disagreeable sensation. Cases giving a history of hearing impairment after diseases involving even the slightest meningeal participation may arouse suspicion for pathology of the ductus cochlearis. The excretion of the endolymph takes place from the saccus endolymphaticus, which is located in the aqueductus vestibuli between two layers of the dura mater, surrounded by loose connective tissue with rich vascularization. When you consider this fact, a meningeal inflammatory process can easily alter the biologic conditions around the saccus endolymphaticus. It has been noted by authors that a hydrops of the ductus cochlearis is frequently associated with a substitution of the mentioned loose connective with scarlike tissue with poor vascularization. It should be pointed out here that there is not sufficient evidence of cases being properly tested and histologically

lasting disturbing effect on the succeeding words

Often the question arises as to which ear should be fitted. There is a difference of opinion as to whether one should fit the better ear, the worse ear, or both ears. It seems that this cannot be anticipated. There are different factors to be considered, pure psychology and psychophysiology. If the patient hears much better with both ears than with either ear alone, it will be better to fit the poorer ear. On the other hand, if the patient hears with one ear and complains of difficulty in hearing, this ear should be fitted. The discrimination as to whether the patient hears binaurally or monaurally is quickly decided by the intelligibility test. In some cases it seems to us that binaural fitting would give the optimum improvement, but the resistance on the part of the patient is far greater in practice than generally supposed. It is very difficult to convince the patient of it.

Testing procedure as adopted by us is as follows. When a detailed history of the patient has been obtained, the patient's ears are examined and the clinical condition is established. The routine test with a tuning fork of 256 cycles is taken. Next is the audiometric test of both air and bone conduction. Not only the sensation of threshold intensities is of interest but the reaction of the patient to higher levels of intensity. The patient is questioned about the quality of the sounds he hears, the description may be that of a pure tone or a rough tone. A pure tone of low intensity may become one of rough quality at high intensity. We desire to know whether the patient can discriminate pitch.

One of our patients, for instance, gave a fair and definite reaction for threshold intensities, but, on being questioned as to what he heard, he described the tones as "low and high whistles." Yet he denied decisively that he could discriminate pitch. He was a professional musician and knew, therefore, exactly what the meaning of the sensation of pitch was. He came to us asking for a hearing aid to give him that sensation. Of course we could not help him. Incidentally, this case is of great theoretic interest because it proves that there may be intelligibility of speech without any discrimination of pitch.

In addition it suggests theoretic considerations about the function of the organ of Corti. The patients are also examined for diplacusis. This is a difficult test, as the average patient cannot discriminate exactly the different qualities of sensation comprised

in hearing. Then follows the intelligibility test based on principles described by Fletcher and Steinberg. It consists in calling numbers, sentences, and syllables under standardized conditions. The reading back of the syllables is of importance, as it is a double check for the perception. Taking the history and the various tests into consideration, one may assume the predominance of one of the four classes described. Accordingly, some one of the available instruments would have the best characteristics of performance to fit the case. The intelligibility test is repeated with the instrument on. The decision in recommending an instrument depends on the result of the intelligibility test. Complete testing takes about an hour, and frequently the patient is asked to come back for another examination. Examinations of this kind are very often fatiguing to the patient and cannot be completed in one sitting. There are two rooms used in testing. One room has a high reverberation and a medium background noise level and has a distance of calling about 20 feet, its testing conditions being similar to the living conditions of the average patient.

The other room is constructed for the special purpose of low reverberation. In it is the audiometer and a loudspeaker connected over an amplifier with a phonograph and a microphone, respectively. The latter arrangement may be used for tests under different noise level conditions and other tests not made in routine practice. In calling tests, the human voice is preferred to phonograph reproduction, the former being more natural. We consider the above described testing the minimum requirement for a conscientious fitting of a hearing aid. If possible, a trial of the instrument is allowed the patient at a place where it is most desired.

Modern hearing aids consist of a radio-tube amplifier, a microphone and a receiver, and a battery arrangement to supply the electric current. It should be as small as efficiency will permit. The amplification should be undistorted or of prescribed distortion. There is a certain minimum requirement of parts in an amplifier that does perform correctly. Parts require space, and the instrument becomes larger. The amplifier works more efficiently and economically with batteries of higher voltage. It is a real art on the part of the manufacturer to compromise with the two requirements, a small instrument and an efficient one. A very important problem is the choice of the receiver. The most common are the crystal,

sound Typical answers are "I understand conversation very well in a quiet room if only one person speaks" "I hear well but I do not understand speech in a noisy place"

Discrimination of speech in auditoriums or in rooms with high reverberation is more difficult for a patient with this type of deafness than for any other Also the background noises, i e, those not connected with speech, mask the usable noises, i e, those connected with speech, more for this patient than for any other type The tuning fork test is characteristic for perceptive deafness, but it will be noted that the patient complains of a disagreeable loudness from a heavily struck tuning fork of 256 cycles, applied by air conduction The same intensity would not be disagreeable for a normal ear The audiogram shows, as pointed out, a gradual loss of sensitivity with increasing frequency The threshold of sensitivity of these patients is not so important as the reaction to tones above the threshold With increasing intensity some patients will note a change of quality of the tone, which becomes rough, and the loudness will soon be disagreeable Interesting observations have been made with the tube-amplifier aid The amount of amplification can be regulated in such a way that when the patient tries it, and turns the aid on a very little, often the following remark will be made "The voice sounds natural but I cannot understand because it is not loud enough"

When the aid is turned on a little more the patient may understand better, but he is not satisfied with the quality He claims that the speech sounds distorted and that a further increase of amplification changes the intelligibility of speech for the worse The patient becomes embarrassed and removes the earpiece Taking into consideration that commercially available hearing aids do not give undistorted stronger amplification, the test was made under better conditions of amplification, and the same reaction of the patient took place The degree of amplification of background noises is of importance in such cases Discussing this picture of nerve insufficiency, one should take into consideration that the nerve usually does not degenerate uniformly, meaning that a certain number of normal functioning nerve elements is present in the degenerating nerve It is probable that the patient hears speech "like music," only as long as the normal nerve tissue is "busy" It is also probable that only normal

nerve tissue can carry sound from the end-organ undistorted to the higher centers

With increasing loudness there will be an increasing demand for nerve tissue Slightly degenerated fibers are different in their biologic reaction, although they are still able to carry out their function Impulses from the endorgan which cannot be transported by normal tissue will be forced to make a slightly degenerated nerve element "busy," and distortion will result Further increase of the number of impulses generated by higher intensity will engage more of the degenerating fibers, and the relationship between busy normal and busy abnormal fibers will soon be in unfavorable proportion for the intelligibility of speech The intensity of sound has to be adjusted between the Scylla of insufficient loudness for proper reception of speech and the Charybdis of distortion due to increased intensity In discussing the principles to be applied in fitting this type of hearing impairment, the first aim will be to protect the nerve from getting too many impulses Second, most of the impulses should be generated from the noise created by voice, excluding background noises as much as possible Hearing aids for these cases should provide more protection from noise than amplification of sound A smooth instrument connected with a crystal receiver and an individual earpiece are recommended The volume should be turned on as little as is required for the understanding of speech

So-called automatic volume control used in some aids prevents sound having a greater intensity from being amplified in the same proportion as sounds of lower intensity This arrangement of specific intensity amplification is advisable for this group Interesting tests have been made showing that there may be considerable amplitude distortion of speech noises without hampering the intelligibility Again these experiments were made on normal ears, and it is a matter of research to establish the appropriate selective frequency and intensity amplification for the deaf ears Special attention should always be given to the low frequencies An economic use of low frequencies would minimize the masking effect In addition, low frequencies are more reverberant in large auditoriums than the middle or high frequencies, thus, a part of the background noise may be eliminated Clicks and sudden noises are a particular nuisance for patients with nerve insufficiency They prevent understanding of speech during their appearance and have a kind of

PERIODONTIA IN INTERNAL MEDICINE

Periodontal Disease, Its Importance as a Focus of Infection and the Possibilities of Treatment

SAMUEL CHARLES MILLER, D D S , F A C D , and ALLAN N ARVINS, D D S , New York City

IN THE search for foci of infection the physician is frequently confronted with the problem of dental conditions that may be responsible factors. Too often lesions of a serious nature are completely missed because of their lack of radiographic evidence, although they may be extremely important foci from which absorption of bacteria and their toxins takes place.

There is still a strong trend toward condemnation of nonvital teeth, even though properly filled. Yet, it has been shown upon histologic examination of some extracted nonvital teeth that the cementum or bone continuous with the alveolar process has completely closed the apical foramen and that the surrounding tissue is entirely free from inflammation.¹

Although the literature on the subject is meager, the following reasons substantiate the authors' opinion that the danger from periodontal foci (pus pockets, gingivitis, etc.) is much more potent than that from periapical disease.

1 A much greater zone is involved than in a periapical abscess, considering the total surface area of the walls of all of the pockets. It can safely be stated that at least twenty times the absorption surface is involved in an average case of periodontal disease than in a well-developed chronic periapical abscess.

2 Absorption from the gingival crevice is more rapid, since the blood and lymph supply to the gingivae is much greater than to a periapical area in bone, especially when the latter is surrounded by even a slight degree of condensation.

Cogan² states "The richness of bacterial flora under the gingival crevices, with large areas of inflammation (having more blood vessels directly in contact with the infection), facilitates entrance of the bacteria into the circulation in sufficient numbers to produce infection."

Round, Kirkpatrick, and Hails³ have shown that the force of mastication is sufficient to pump bacteria and their toxins into the blood stream.

Rosenow⁴ reports "Elective localization of streptococci isolated from pyorrhea pockets occurred commonly following intravenous injection, thus emphasizing the importance of periodontoclasia as a focus, and steps to correct this most common of evils should be taken."

3 Resistance to bacterial growth is lower in the gingival crevice than anywhere else in the oral cavity because of stagnation and food accumulation.

The zones of greatest susceptibility in the mouth have been studied by Stuart, Knudson, and Arnold,⁵ who report that "the lips, gums, and tongue seem to have an inexhaustible supply of bacteria, both in numbers and in strains. There is little if any spread of transient bacteria from the lips, gums, and tongue when the mouth is held in an almost fixed position, but with mechanical movements of the cheeks and tongue these organisms rapidly travel, primarily backward towards the throat and pharynx."

Billings⁶ states "the strains of streptococci which apparently cause chronic deforming arthritis and myositis grow best in a low oxygen tension, and even grow anaerobically." The depths of gingival crevices and periodontal pockets offer an ideal incubation zone for these types of organisms.

It thus becomes imperative that any complete search for foci of infection include attention not only to radiographically evident lesions at the apices of teeth but should encompass, with even more care, the radiographic study of the alveolar margin for activity of bone destruction, as well as a thorough clinical examination for gingival disturbances which may possibly not as yet have affected the bone structure.

The amount of bone loss is not so significant to the periodontist as the type of bone which remains, for this determines the activity of periodontal disease. One of us (S C M) has classified the alveolar bone in periodontal disease for ease of diagnosis as follows:

1 *Normal Alveolar Support*—The alveolar process is of even density throughout. There is an even distribution of light and dark shadows (the cancelli and medullary spaces of alveolar bone). The crest of the alveolar wall

Associate professor of periodontia in charge of Periodontia Department, and instructor of periodontia, respectively, New York University College of Dentistry

the magnetic, and bone-conduction receivers

The latter may often be replaced with advantage by a magnetic air receiver, which is connected with an individual ear mold made from lucite or other plastic material. As pointed out, the amount of sound conducted to the ear by bone seems to be high by this arrangement. We do not doubt that the construction of the magnetic receiver will be of importance for the future development of hearing aids. Crystal receivers are built on the principle of the piezo-electric effect of Rochelle salt crystals. They are advantageous in cases where reproduction of high frequencies is most desired. They are light in weight, have smooth reproduction of sound, but are not stable under hot climatic conditions. Although the principle of all radio-tube amplifiers is the same, the characteristics of performance of every make and even of every instrument is different. It is, therefore, of importance to the acoumetrist to have available as many instruments as possible in order to give the best fitting.

The patient should be encouraged, after he has acquired a suitable hearing aid, to make use of lip reading, which he has consciously or unconsciously acquired through the years of his deafness. In those cases that cannot be fitted, where the patient is beyond relief by an electrical instrument, speaking tube, or horn, lip reading is the best and often the only means of communication with the outside world. Leagues for the hard of hearing, which are established in most cities, give much of their time and effort to teaching lip reading on a charitable basis. The teaching of lip reading is a profession in itself which is best taught in one or other of the lip reading schools in the country or by private teachers in the art.

Organic changes represent only a part of the complex problem of the hard of hearing, and psychologic experience is an important pre-

requisite in dealing with these patients. But it should be borne in mind that it is the duty of every acoumetrist to crystallize all organic changes as clearly as possible. Only on their knowledge can the best fitting be provided.

Summary

An attempt is made to classify hearing impairments into four classes for the purpose of fitting hearing aids. The classification is made on the basis of physiology and pathology of sound transmission and sound perception. Although isolated forms are rather rare, one of the classes of hearing impairment is usually predominant in every ear with abnormal function.

There are certain characteristics of amplifiers and receivers which are better suited for any of the classes of impaired hearing.

The importance of the type of the receiver is stressed.

It is pointed out that the fitting of deafened and hard-of-hearing patients can be done only by specialized persons. Acoumetrists should be trained and licensed just as optometrists are.

DOCTORS ARMED TO THE TEETH

Beginning with the fall of 1941, Harvard University will inaugurate a new five-year course in its renamed School of Dental Medicine. Graduates in this new course will receive both the M.D. and D.M.D. degrees.

FIG 5 Radiograms illustrating rapid bone destruction—(a) anterior region, (b) posterior region

B—Underfunction.

- 1—Nonocclusion.—Two or more opposing teeth do not make contact with each other in any of the excursive relations
- 2—Premature wear.—The morsal surfaces are worn too rapidly either through a coarse food diet, an acid decalcifying environment, or improper artificial shaping of the teeth or restorative procedures. In such cases the periodontium does not receive sufficient functional stimulation through pressure on the cusp inclines in chewing

C—Abnormal habits

- 1—Unilateral mastication.—This may be initiated by a painfully erupting third molar, a missing tooth, a sensitive cavity or some inefficiency of the teeth on one side, creating a habit of chewing on the other side. The result is loss of tissue tone and disease of the insufficiently used side.
- 2—Abnormal biting habits.—The biting on foreign objects or materials for which the teeth are not intended, e g, fingernail-biting, pencil-biting, lip-biting, thread-biting, etc

II—Irritational.

A—Calculus

- 1—Supragingival (salivary)
- 2—Subgingival (serumal or serumal)

- B—Improper toothbrushing.—Vertical, rotary or crossbrushing can produce gingival disease. Massage of the gum tissue by the toothbrush, improperly performed, not only is of no value but often is damaging

C—Food impaction.

- 1—Vertical.—The forceful wedging of food against the gum tissue by chewing pressure
- 2—Horizontal.—The pressing of food into the spaces between the teeth through the action of a powerful tongue or by buccal and lip pressure when the vestibule is narrow or when the teeth are improperly arranged.

- D—Effect of cavity margins, improper inlay or filling margins, orthodontic appliances, or bridges or dentures which impinge upon or irritate the gingivae.

Fig 1 Radiographs illustrating normal alveolar support—(a) anterior region, (b) posterior region

Fig 2 Radiographs illustrating marginal thickening of the peridental membrane indicating inception of periodontal disease

Fig 3 Radiographs illustrating arrested bone destruction—(a) anterior region, (b) posterior region

Fig 4 Radiographs illustrating slow bone destruction—(a) anterior region, (b) posterior region

is protected by the lamina dura which surrounds it and dips down to line the alveolus, leaving a thin dark line or space occupied by the peridental membrane (Fig 1). At this time, radiographically, there is no suspicion or prediction of disease.

2 Marginal Thickening of the Peridental Membrane Line with Thinning of the Peridental Lamella or Lamina Dura (Fig 2)—This indicates the beginning of periodontal disease and will enable the observer to predict by five years the actual clinical appearance of the disease. It is the radiographic equivalent of rarefying pericementitis fibrosa as described histologically by Box.⁸

3 Arrested Bone Destruction—The bone crest is at a lower level than normal, but the alveolar bone is of even texture throughout, presenting the same density up to the margin of the bone. The height is dependent on the amount of destruction that has previously occurred. If destruction is arrested for some time, there is a new, dense, white line over the remaining crest of the alveolar process which continues to form the peridental lamella or lamina dura (Fig 3).

4 Slow Bone Destruction—The level of the bone crest may vary and is not an important consideration in determining the rapidity of bone dissolution. When the peridental lamella is absent over the alveolar crest and

there is a darkening of the alveolar process penetrating only a short distance into the bone septum, it may be considered that a slow destructive process is under way. Beyond the shallow area of penetration, the remaining alveolar process is of uniform density (Fig 4).

5 Rapid Bone Destruction—In this situation the peridental lamella or lamina dura is already destroyed, and there is a gradual darkening of the alveolar bone, increasing toward its present crest. The bone gradually fades into the darkness of the soft tissue covering it. The greater the depth of penetration of this shading into the alveolar process and the more gradual the diffusion from the darkened area to the lighter structure of normal bone, the more rapid the decalcifying process (Figs 5 and 6).

Periodontal disease is primarily dysfunctional in origin, the disturbing factors producing a "locus minoris resistentiae." From a practical point of view, the etiologic factors may be grouped as follows:

I—Functional

A—Overfunction.

Occlusal trauma

- 1—Excessive stress on teeth.
- 2—Insufficient periodontal support.
- 3—Too powerful masticatory musculature

FIG 5 Radiographs illustrating rapid bone destruction—(a) anterior region, (b) posterior region

B—Underfunction.

FIG 8 (c) After five visits consisting of subgingival curettage, advice on diet and toothbrushing and, when the hypertrophy receded, balancing of the occlusion. Note that spaces between teeth have reduced markedly (d) Lingual view as shown in Fig 8(b) after five visits. Note improvement without surgery

ing rules for choice of procedures have given greatest benefit in our hands

a *Surgical Gingivectomy* (removal of affected tissues, e.g., Ward, Black techniques, electrocoagulation, etc.)—This procedure should be resorted to only on lower molars in exceptionally well-kept mouths, when the bifurcations are involved by the infective process and it is necessary to save these teeth for attachments of bridges or to preserve arch continuity

b *Conservative Surgery* (exposing the affected area for access and returning the overlying tissue to place after the operation, e.g., flap operation and Kirkland, Hoffer techniques)—These procedures are of advantage in instances where access to the pocket cannot be obtained with conservative treatment. These are the tortuous pockets and those widening out greatly at the fundus. A button-hole incision is often sufficient for these cases and avoids the possibility of marginal recession. This is made vertically over the deeper part of the pocket to about 4 mm. from the gingival margin. The deeper part is curetted through the incision, and the superficial part is curetted through the marginal crevice. Thus, no recession is produced

c *Conservative Subgingival Curettage*—This is the procedure of choice because of the possibility of reattachment and a return to the normal gingival contour. There is little loss of tissue and the performance of the operation produces minimum discomfort, local anesthesia is rarely needed. The operator must become skilled in the manipulation of curets and deep pocket scalers, but this dexterity can be developed with

FIG 9 (a) Mouth of woman, aged 38, showing very poor gingival tone with irregularity of gingival margin. Note upper left lateral incisor in linguoversion and the unesthetic form of the teeth. (b) Same case after treatment. Note improved tone and regularity of gingival festooning. The upper left lateral incisor is practically in line due to healing without any resort to orthodontic procedure. Also note the improved form of the teeth. Conservative treatment was employed

practice by anyone capable of successfully performing other branches of dentistry

Summary

- 1 Periodontal disease is a more potent focus of infection than periapical disease
- 2 The presence of periodontal disease may be predicted radiographically several years before its actual clinical appearance
- 3 An original classification of alveolar types revealing the activity of bone destruction is presented
- 4 The etiologic factors of periodontal disease are known. Rarely, if ever, is a single factor responsible
- 5 Periodontal disease can be cured, and the state of health thus produced can be maintained
- 6 Procedures in successful treatment of over 15,000 cases are presented

FIG 8 (a) Hypertrophic gingivitis, before treatment—boy, aged 17 Note spreading of teeth due to pressure of hypertrophied tissues The teeth cannot occlude because the enlargement of the gum tissue on the lingual of the upper anteriors makes contact with the lower anteriors (b) Lingual view, same case, showing hypertrophy which kept the upper and lower teeth from making contact.

C—Endocrine disturbances

D—Allergies and idiosyncrasies manifested in the periodontal tissues

E—Nervous disorders

- 1—Sympathicotonia or parasympathicotonia (vagotonia) may be responsible for disturbance in local blood supply
- 2—Interference with absorption and assimilation of necessary dietary agents, e g, minerals, vitamins
- 3—Neurotrophic disturbance, interfering with the nutrition of the periodontal tissues
- 4—Bruxism (rubbing of teeth together during sleep) and bruxomania (habit of gritting teeth)¹⁰

Since bacteria are secondary factors in the production of periodontal disease, the use of vaccines, antiseptics, and germicides have little influence in periodontal treatment. However, autogenous vaccines derived from organisms taken from the periodontal pockets may be of great benefit in the treatment of related systemic disturbances after the local disease has been eliminated (Vaughan¹¹ and Burbank¹²).

At the present stage of development of periodontology it may safely be stated that periodontal disease is curable. An editorial in the *Journal of the American Dental Association* of August, 1935, states "The most surely fatal edict that has ever been permitted to go out in connection with this subject is to the effect that 'pyorrhea cannot be cured'. Of course it cannot be cured, provided the disease has gone so far that the tissue around the tooth has nearly all been destroyed and the hapless member is left prone and wobbling, without maternal support of any kind in a mass of flabby and unregenerate tissue. Miracles are not performed in this latter day,

though the manner in which teeth tighten and become firm and serviceable when the cause is discovered and the proper remedy applied surely borders on the miraculous."

The following procedures have been found successful in the treatment of over 15,000 cases in clinic and private practice by members of the Periodontia Department of New York University College of Dentistry.

1 The primary procedure is the restoration of functional coordination of the teeth in such a way that stresses are evenly divided and that there is no strain in any of the excursive movements. This is usually done by shaping the teeth to their proper functional form by means of a carborundum stone. In some cases where teeth have been excessively worn, it may be found necessary to rebuild one or more of the posterior teeth by means of onlays and even, on occasions, to construct porcelain jackets for the anterior teeth. In young individuals, orthodontia may be beneficial. In some instances the combination of grinding certain teeth and placing restorations on others is necessary. Orthodontia, when performed on adults, should always be followed by the shaping of the teeth to conform with the patient's age-form according to functional requirements (Fig 7).

2 Attention must also be given to the possibility of dietary deficiencies or systemic diseases which may be causing or complicating the local disease. It is in this field that most can be gained from medicodental cooperation.

The direct local requirement of a fibrous, detergent diet is of equal importance to the mineral, vitamin, and other fundamental dietary requirements for oral health.

3 Elimination of the pocket. The follow-

THE ORGANIZATION OF AN ARTHRITIS CLINIC

With Special Reference to the Arthritis Clinic at the Hospital
for the Ruptured and Crippled, New York City

R. GARFIELD SNYDER, M D , F A C P , and CORNELIUS TRAEGER, M D , F A C P ,
New York City

UP TO thirty years ago there were no special arthritis clinics in America—at least there is no record of one. Apparently the first in this country was established by Dr. Ralph Pemberton in 1911, in conjunction with Miss Frances Hostetter, at the Presbyterian Hospital in Philadelphia.

The first arthritis clinic in New York City was established by Dr. Reginald Burbank at Cornell University in 1917. Dr. Burbank established another clinic at Bellevue Hospital in 1919, and Dr. Russell Cecil took over the Cornell clinic. In 1924 one of us (R. G. S.) established the arthritis clinic at the Hospital for the Ruptured and Crippled. There is no authentic information about the number of these clinics existing in America, but there are probably many small ones that are not officially known, as only the relatively large clinics have the facilities for obtaining accurate scientific data suitable for publication.

As evidence of the rapid development of interest in arthritis in New York City during the past twenty years, a recent survey, made by the Committee on Arthritis of the Welfare Committee of the City of New York, has shown that there are twenty-one special arthritis clinics in Manhattan and the Bronx and six in Brooklyn. At the present time, New York City and Boston lead other cities in the number of these clinics.

Arthritis clinics are variously located in university hospitals, general hospitals, and in orthopedic hospitals—each with its certain advantages and disadvantages.

University hospitals usually offer a better opportunity for conducting chemical research and animal experimentation, which is essential for determining the therapeutic as well as the toxic properties of the different forms of treatment. These university clinics are, therefore, of great importance in advancing our knowledge of the scientific indications and contraindications in the treatment of the disease. Unfortunately, there are relatively few university hospital clinics in the country, and they care for only a small percentage of the total number of patients needing treatment. In the second place they often restrict

their investigations to the forms of arthritis that happen to interest the full-time workers or investigators who control the policy of the clinic. All other forms of arthritis are apt to be eliminated from consideration or referred back to the general medical clinics for treatment. This policy is hardly fair to the patient suffering from one of the many other forms of arthritis, and the practice of restricting the admission of patients to only one form of arthritis cannot but narrow the practical experience as well as the perspective of the men working in the clinic.

An arthritis clinic located in a class A general hospital has many obvious advantages. There are many more general hospitals than either university hospitals or orthopedic hospitals. The general hospital has a large staff of specialists and internists, which makes possible a thorough study of each case. Unfortunately, not all well-trained internists are interested in the arthritis problem and, therefore, are not well qualified to treat arthritis patients.

An arthritis clinic located in an orthopedic hospital has certain advantages over the arthritis clinics located in either university or general hospitals, because every arthritis patient is potentially or actually an orthopedic problem and, therefore, requires the closely coordinated efforts of both the internist and the orthopedic surgeon.

It is our opinion that the ideal location for an arthritis clinic is in an orthopedic hospital, because of its well-equipped laboratory, x-ray, and physical therapy departments, the latter department being an essential component of any good arthritis clinic.

In the early stages of arthritis, deformities can often be prevented by taking the advice of the orthopedic surgeon on the use of the proper appliances. In still other cases orthopedic measures give support to weakened structures or otherwise overcome abnormalities causing some of the arthritic symptoms. In the later stages orthopedic surgery can often improve marked deformities so that the patient regains some degree of use of the limb.

It is true that a university clinic or a clinic

Conclusions

1 The physician should be more familiar with the periodontal problem and its association with systemic disease

2 Closer medicodental cooperation is necessary for the most efficient control of this disease

Announcement—Change of Address

It is urgently requested that when members make permanent changes of address they notify

- 1 Secretary of the County Society
- 2 This office of the State Society—292 Madison Avenue, New York City
- 3 Director of the Division of Professional Education, Mr Charles B Heisler, State Education Dept, Albany, New York, who has charge of reregistration

Prompt action will help the county societies, will save payment of forwarding postage for the NEW YORK STATE JOURNAL OF MEDICINE, and will keep up to date the list of registered physicians maintained by the State Education Department. It will obviously be to the interest of the physicians concerned.

From Mr Heisler has come in the following request, which applies not only to the members but to all the physicians registered in the state, nonmembers as well as members

"Dear Dr Irving

"With the information that we receive we do all that we can to keep up to date our address list of registered physicians. Nevertheless we find each year that many of the addresses are incorrect because we have not received notice of a change in his address that a physician has made. I fully realize that physicians are quite unaware that notice of a change of address is important to us, unless they are specifically advised to that effect.

"I wonder whether you would be willing to insert a notice in the NEW YORK STATE JOURNAL OF MEDICINE to the effect that it will be of much help to us in carrying out annual registration with the minimum of trouble to them and in sending them the printed list of registered physicians, if each of them will be good enough to let us know whenever he changes his address.

CHARLES B HEISLER"

Peter Irving, M.D., Secretary
292 Madison Avenue, New York City

in a general hospital often has an orthopedic surgeon on its staff, but his services can hardly compare with the collective experience of a whole orthopedic service as found in an orthopedic hospital

Most orthopedic hospitals occasionally call in a consulting staff for their nose and throat, dental, gynecologic and urologic services. We know from experience that the only way to obtain proper examinations in an active arthritis clinic is to have the required specialists appointed to the staff of the arthritis clinic and have their hours coincide with the hours of the clinic. Only such a well-knit, closely regulated clinic produces the best results

It is, of course, essential that the various specialists who examine arthritic patients keep in mind that these people may have no complaints referable to their specialties. Therefore, their search for foci of infection should be more careful than in patients who present themselves to these specialists with more obvious pathology. The experience that these specialists acquire in examining these patients and talking over the relative importance of foci of infection with the internists on the staff of the clinic eventually makes for much better judgment on the part of both the internists and the specialists in the handling of these cases

The Arthritis Clinic at the Hospital for the Ruptured and Crippled, started in 1924, was one of the first to initiate the scientific study of all forms of arthritis. At first the staff of the clinic consisted only of one of us (R. G. S.) and a secretary. During the past sixteen years it has gradually developed, until now there is a staff of twenty-five physicians and nine nonprofessional assistants. The growth of this clinic is proof that it is possible to establish an efficient clinic in any class A hospital in America, providing the hospital is located in a relatively large city. A detailed description of this clinic follows, for we believe that its organization may interest those considering the establishment of an arthritis clinic

Details of Organization of the Clinic

It is obvious that the chief of the clinic should be well trained and have a wide experience and deep interest in the disease. In addition to medical qualifications, organizing ability is important. The duties of the chief of the clinic and also those of his associate include going over each case carefully after it has been worked up and deciding in

consultation with the physician in charge of the case the best form of treatment to employ. Later, if the patients are not satisfied with the treatment they are getting, it is their privilege to take their complaints directly to the chief of the clinic or to the associate chief. In a well-organized clinic, complaints of this type are only rarely encountered

Next in importance in the arthritis clinic is the caliber of the medical staff, whose duty it is to examine the patients and carry out the treatment. The medical men should be not only well-trained internists, deeply interested in the study of arthritis, but their personalities must be adapted to the care of patients who suffer from a chronic disease that makes them introspective and sensitive

It is important that all members of the staff attend the clinic regularly and remain throughout the entire two-hour session. Staff conferences are held at regular intervals during the year for discussion of cases and clinic problems

In the clinic we accept all patients who suffer from some form of arthritis or any of its allied conditions. In general, this includes all cases commonly described as rheumatism

We have found it important to limit the number of admissions to the clinic. An unduly large attendance necessitates hasty examinations, curtails the service which should be rendered each case, and results in ineffectual care. It has been found from experience that one man can care for about 2 new patients and 10 old patients in a clinic period of two hours

The chief of the clinic or a physician designated by him passes on the eligibility for admission of the patient and has the privilege of refusing patients he considers unsuitable for treatment. Regular attendance of patients is essential to their proper care. Patients referred for opinion only are not enrolled on the active list. An appointment system is indispensable to avoid overcrowding at any one session.

The record of the patient's history, physical examination, subsequent visits, and social history is kept as part of the routine hospital records. The nomenclature adopted by the American Association for the Study and Control of Rheumatic Diseases is followed as closely as possible for statistical purposes

At least 80 per cent of our cases improve in a satisfactory way as ambulatory patients. This is an important consideration at the present time, because a large majority of our patients are in the low-income brackets and

siderable expenditure of money for an efficient follow-up system, for this involves a great deal of time and detail. But we have proved beyond a doubt that it is this financial outlay that promotes the best interests of the clinic. It not only enables us to estimate accurately the results of our treatments but the financial outlay entailed in a follow-up system is many times repaid in the increased attendance of the clinic.

Our system is in charge of two special secretaries assigned to the clinic who work in conjunction with the Social Service Department.

The following method has been found to be excellent. If the patients do not return for two consecutive visits, a postal card is sent. If after ten days the patients do not return, another card is sent, ten days later, a letter is sent. If there is still no response, a social worker pays a visit to the home. In this way we are able to find out the reasons for non-attendance and, wherever possible, to remedy the cause for the absence. When the patient is discharged, his name, number, and address are placed on a card in the follow-up file. In six months a letter is sent inviting the patient to return for evaluation of results of therapy. This procedure is continued for at least five years and results in bringing to light interesting and important information. Even this is not complete enough, because patients move and it is difficult to trace them in a large city. We are trying to get the patients to cooperate in notifying us of changes in address.

We wish to acknowledge our indebtedness to Dr. H. A. Nissen, of Boston, for the institution and perfection of this follow-up system. On several occasions he has visited the Arthritis Clinic at the Hospital for the Ruptured and Crippled, at which time he has made valuable and helpful suggestions. Anyone interested in an ideal follow-up system should read his article, "The Continuous Follow-up Department of the Modern Hospital," in the *New England Journal of Medicine* for December 6, 1934.

Research

Progress in arthritis therapy, like all other branches of medicine, depends on carefully controlled research. By carefully studying each patient's condition and progress and accurately recording the data, a certain amount of good clinical investigation can be conducted in the regular sessions of the arthritis clinic. Because such clinics are primarily for the care of all sufferers of arthritis, it is not easy to test accurately the efficacy

of various therapeutic agents in a regular arthritis clinic. For this reason we have found it necessary to establish a special research clinic, because much more intensive and valuable research can be done by carefully selecting desirable patients who are to go to the special research clinic for the study of some particular problem related to the treatment of arthritis. For evaluating various therapeutic measures, it is necessary to follow a carefully planned routine. Since a large majority of cases of less than one year's duration may be cured by various therapeutic measures, they may give false value to any therapeutic agent used. To eliminate this criticism, we select cases of at least two years' duration which have proved resistant to the many recognized forms of therapy. By taking accurate measurements, complete laboratory and physical examinations, motion pictures, and x-rays before, during, and after treatment, we have been able to keep an accurate and honest record of the progress of each patient. It takes a long time, as long as two years, to care properly for such patients, and, in order to keep the patient attending this research clinic regularly, we furnish free medication and laboratory and specialists examinations.

Animal experimentation and intensive chemical research require more laboratory space and equipment than is usually available in a hospital. If such work is an essential part of the clinical investigation, it can be satisfactorily done at a university by the hospital's financing the project.

Recently, a committee appointed by the American Rheumatism Association—consisting of Dr. Ralph Boots, chairman, Drs. Walter Bauer, Homer Swift, Loring Swaim, and Robert Osgood—has been working on what is considered by the committee to be the minimal requirements for an arthritis clinic. Up to date, however, these requirements have not been formally adopted, but it is probable that they will be in the near future. When they are adopted, it will be easy for the large cities to form local arthritis societies, because undoubtedly there will be several arthritis clinics in the large cities that will meet the minimal requirements. It is worthwhile to note that Philadelphia has already pioneered in this direction—the Philadelphia Rheumatism Association was established at least three years ago. It is our opinion that all arthritis clinics should be graded much the same way as cancer and general hospitals are graded. These arthritis clinics should then be recog-

cannot afford to be hospitalized where there are no free beds

In our opinion an ideal arrangement is to have a number of free beds available in the hospital with which the clinic is connected. This facilitates the detailed study of certain cases by the staff of the arthritis clinic.

In our hospital the following facilities are at the disposal of the Arthritis Clinic for consultation, diagnosis, or treatment: (1) laboratory service—(a) biochemical, (b) serologic, (c) bacteriologic, (d) pathologic, (2) roentgenologic facilities, (3) physical therapy department, (4) special consultants—genito-urinary, otolaryngologic, gynecologic, dental, etc., (5) photographs, including moving pictures of each new patient—50 to 100 feet in all positions and walking, and (6) occupational therapy.

Nursing Service—The nursing service of the hospital is responsible for carrying out nursing procedures of the clinic.

Social Service—The primary duty of the social service is to supplement medical with social treatment. This aids the physician in dealing with such conditions as the patient's home situation, occupation, or mental attitude—those things that require adjustment in order to make medical aid effective. As soon as possible after patients are enrolled, they are visited by a social-service worker who completes the social record and adds it to the case history. The social-service workers in the arthritis clinic are directly responsible to the director of the social service of the hospital. They are present during the entire clinic session and are of great assistance to us in our follow-up system, as will be shown later.

While our clinic is primarily a pay clinic, we are able to take care of a limited number of free patients by special research grants. All cases referred to us from the orthopedic department of the hospital are given special consideration, and every effort is made to adjust fees to meet the financial status of the patients. No patient from this source is sent away until the chief of the clinic or his associate has reviewed his financial condition. Likewise, cases applying to us from outside sources are always given a sympathetic hearing and aid, if possible.

It saves the physicians' time to have a specially trained nurse to take histories and to obtain complete data for future statistical records. The examining physician takes her record but asks his own questions in order to bring out pertinent facts.

Following the completion of the physical

examination, the patient is referred routinely to the laboratory for complete blood chemistry studies, Wassermann, sedimentation rate, complete blood count, and urinalysis. It is essential that the laboratory work be as complete as the physical examination. If the need arises, other blood chemistries are done: cholesterol, phosphorus, phosphatase, and other diagnostic procedures as basal metabolic rate, x-rays, electrocardiograms, etc.

When the reports of the various specialists are completed, the positive facts having a bearing on the diagnosis of the case are listed as the positive objective findings.

We have found that at first it is wise to follow, as a routine, those forms of treatment which in our experience are of proved value. If after three months the patient shows no improvement, we then place him on various forms of special treatment. Sometimes these are referred to as treatments of unproved value. In difficult or refractory cases these special treatments often bring about successful results where the more conservative forms have failed. While these special treatments are often more spectacular in the therapeutic results obtained, it is also true that they are often more dangerous. For this reason it is advisable to have one physician in the clinic assigned to carry out each of these treatments because the experience he acquires enables him to administer the treatment with the least possible danger and the greatest possible efficiency. For example, one internist is assigned to treat all the patients under gold, another, high potency vitamin D, another, vaccine therapy, etc. The physician sees his patients at weekly intervals and changes the therapeutic regimen as the need arises after consulting with the chief or associate chief of the clinic.

Follow-Up System

One of the most important aspects of an arthritis clinic is the follow-up system. Instituting this service has proved to be an excellent thing for the hospital and invaluable for several reasons. The patients are impressed with the interest shown, it serves as a reminder of appointments, and it stimulates, in the patients, a more cooperative spirit. This cooperation is absolutely essential to the physician in evaluating any type of therapy and compiling statistical data, and, of course, faithful attendance is highly necessary if the physician is to accomplish desired results.

Ordinarily, it is very difficult for hospital executives to realize that it requires a con-

ROENTGEN-RAY THERAPY OF PLANTAR WARTS

ANDREW H. MONTGOMERY, M D , and ROYAL M. MONTGOMERY, M D , New York City

AS EVIDENCE of the growing importance of these painful, disabling, common lesions there have been several reports of their treatment by roentgen rays in American and foreign literature in the last ten years. Notable among these are articles by Osborne and Putnam,¹ Leddy and Johnson,² Standish,³ Klapproth,⁴ Marques,⁵ Popp and Olds,⁵ and Belot.⁷ But in none of these is there to be found any differentiation as to the types treated. No uniform plan is offered as to dosage. Some recommend large doses at long intervals. Others use smaller doses at shorter intervals. The majority report the use of unfiltered rays, with occasional references to filtration.

We believe that the following report is justified by the fact that in a large series of private patients, 583, a very large percentage of cures was obtained by roentgen-ray therapy alone without the slightest disability having been caused. No person was laid up a single day on account of the treatment. There were no regrettable sequelae. There were no recurrences.

Unfiltered rays were used throughout this series, the horny tissue absorbing to a great extent the soft and medium rays. An unfiltered skin unit, according to the calibration of our machines, equals 340 r. Radiation is generated at 87 kilovolts 3 milliamperes with a skin-target distance of 8 inches, kenotron rectification.

With one or two exceptions larger doses were used than have been reported previously. The interval between irradiations was less than in any other series, but, because of the technic developed (that of very close and increasingly contracted shielding), not a single case of radiodermatitis has ensued.

Moreover, our series is unique in that we were confronted in the majority of cases with lesions that had resisted therapy by more or less skilled operators using caustics, local and intramuscular injections, electrocoagulation, surgical diathermy, etc. Many were recurrences after surgical excisions. Their stubborn nature is shown by the fact that the average duration of our warts before roentgen therapy was over eleven months.

We have excluded from our list some 140

cases of mosaic warts (Figs 1 and 2), insensitive patchy types with ill-defined borders, described by us three years ago⁶ as decidedly radioresistant. As proof of their resistance to radium, roentgen rays, and other common modalities, many patients have come with areas of radiodermatitis, irradiation ulcers, and permanent damage to the plantar fat pad (Fig 3). These unfortunate avoidable results were an added incentive to the writing of this paper.

There seems to be much inexcusable error in the diagnosis of plantar warts. Those under pressure points are usually surrounded by, or imbedded in, callus. A roughened central mass in an encircling smoother callus should call for investigation. Deviation from the normal arrangement of papillary lines should make one suspect the presence of a wart. In callus the normal ridge and furrow system is maintained. Upon superficial paring of a wart, one finds an oval, rounded or multilobular mass, varying in color from the normal skin and sharply limited from it by a light, often transparent horny membrane. In this central mass are visible, minute, dark points—coagulated blood in the tips of enlarged papillae (Fig 4). Further paring opens these tips causing capillary hemorrhage.

This vascular condition is entirely absent in a corn or in callus, but occasionally it may be simulated in those intensively painful lesions, popularly called neurovascular corns, located beneath prominent metatarsal heads usually in hyperthyroid individuals. In these growths hypertrophied blood vessels may be seen through the transparent horny layer lying parallel with the surface. Close examination may reveal minute superficial fissures. We have many photographs of ulcers caused by persistent irradiation of these lesions.

Our list includes some cases of the infective or epidemic type of plantar warts—multiple lesions, usually bilateral, found most commonly in young people. They may be inflamed and painful and are often accompanied by hand warts. These are curable by any destructive method. A roentgen dose of 1 skin unit usually is adequate. This form of wart responds to various kinds of injection therapy. In children from 8 to 18 years of age it is this type, and this type only, which

nized, not only by the American Rheumatism Association, but also by the American Medical Association, the American Orthopedic Association, and the American College of Physicians

Finally, great credit should be given first to the American Committee for the Study and Control of Rheumatism and second to the American Rheumatism Association for the progress that has been made in the last ten years in organizing and promoting better and more efficient arthritis clinics. At the same time they have done much toward increasing public interest in the study of arthritis.

It would be desirable to have at least one or two hospitals in the United States devoted entirely to the study and treatment of arthritis—hospitals modeled after the Memorial Hospital in New York City, which is devoted to the study and treatment of cancer. As arthritis is twice as common as tuberculosis and ten times as common as cancer, it would not seem that this is too much to ask. However, despite the need for such an institution, two objections are often raised by various members of the medical profession. The first is the fact that, although the personnel of the staff would be enthusiastic at the start of the establishment of a separately maintained hospital, there is always the possibility of a lapse of enthusiasm as time goes on. The second objection is the matter of finances and the maintenance of special laboratory, x-ray, and research facilities.

It is our opinion, in answer to the first objection, that enthusiasm would not lapse because of the great need for work of this kind. The amount of enthusiasm displayed by the staff of any hospital depends upon the organizing ability, the vision, and the enthusiasm of the chief of staff. Second, in regard to finances and the maintenance of laboratory and x-ray facilities, it is obvious that at the present time any class A hospital must have up-to-date, well-equipped x-ray and laboratory departments. If research is necessary, it can be done, as has been mentioned before, at university hospitals where equipment for research is provided.

At the present time it is difficult for the arthritis patient to know where to go to ob-

tain the highest type of treatment. No arthritis clinic, regardless of its efficiency, can be brought to the attention of the public as well as a hospital devoted exclusively to the treatment of arthritis.

In the future we will probably have to have three types of arthritis clinics. One type, called Research Clinics, would be limited to university hospitals, because they can not only furnish very exact clinical statistics but they can also have these investigations correlated with reliable and detailed bacteriologic, chemical, and animal experiments.

The second group of clinics could be organized for clinical research work in arthritis, their scientific reports should be strictly limited to clinical investigation as to the value of new forms of therapy in arthritis.

A third type of clinic could be developed in any well-equipped general hospital regardless of size, locality, or equipment if at least one member of the staff is assigned to take care of the arthritis problem in the hospital and if an attempt is made to build around him a modest arthritis service. These clinics should be headed preferably by an internist. He could easily keep well informed regarding changes in the trend of thought and therapy pertaining to the arthritis problem by carefully reading the "Rheumatism Review" published annually in the *Annals of Internal Medicine* and by an occasional visit to one of the larger and more ideally equipped clinics.

The problem of the proper care of arthritic patients should, to a large extent, be cared for by the general practitioners, as 60 per cent of all arthritis cases are fairly easily cured. The necessity for establishing more special arthritis clinics can easily be seen from a careful study of the following statements. Of the seventy-seven medical schools in the United States which are recognized as Class A medical schools, only a minimum number of these have any special course in arthritis or any clinics devoted exclusively to the treatment of arthritis. To the best of our knowledge only two postgraduate schools in this country give instruction in arthritis, and throughout the United States there are no hospitals devoted exclusively to the treatment of arthritis.

SOMETHING TO REMEMBER

The doctor who appears on the witness stand not only speaks for himself but represents the entire practice of medicine. His manner, the opinions which he voices, the scientific knowl-

edge, and the interest in the case as a whole stands out conspicuously to the honor or to the discredit of all medicine.—*Cleveland Academy of Medicine Bulletin*

FIG 3

FIG 4

FIG 4 Verruca plantaris under pressure point showing sharp limitation and capillary tips

the neighborhood of the fourteenth day, that $87\frac{1}{2}$ per cent of the dose is lost in ten and one-half days, and that the destructive effect is relatively brief, becoming at first simply inhibitive and, finally, with loss of ray effect, passing to a phase of stimulation wherein the influence is directly opposed to the effect desired. Recent careful experiments, however, "have never detected any actual stimulating effects, for any dose whatever."¹⁶

Ten days after the initial dose, approximately 85 per cent or four-fifths of it is necessary to bring the effect to the saturation point. At this interval there is no danger of any accumulation effect, and the maximum action is more continuously maintained.

One other important factor obtains in our technic. Undoubtedly the safety attending the use of frequent large doses depends upon our habit of very close shielding. In contrast with the custom of wide shielding in raying cutaneous malignancies, we shave plantar warts until the exact outline of the lesion can be marked in ink. A hole in lead sheeting is cut just the precise size and shape of the inner part of the ink-line. This shield, about $2\frac{1}{2}$ inches square, is fastened in position with strips of adhesive plaster. Large lead sheets of $\frac{1}{16}$ inch thickness with larger holes over the shield-hole are so placed as to protect the foot and limb. A lead-rubber mat covers the other limb. An initial dose, its size depending upon factors to be mentioned, is then given.

Ten days after this first dose when there is usually found, on paring, desiccation of superficial capillaries, distinct contraction of the

size of the wart, and relief of pain, a smaller shield-hole is cut to fit exactly just inside the contracted border. A dose four-fifths that of the first one is then given. This process may have to be repeated several times, using the same four-fifths dosage through gradually contracted holes, the purpose being to focus on and to destroy the central afferent blood vessels and nerve filaments and to avoid raying normal tissue about the rounded base of the wart. Through a hole less than $\frac{1}{8}$ inch in diameter the rays are dissipated and have little effect.

Because of the use of gradually contracted shielding, there does not occur any inflammatory reaction, pain, or subwart puffiness. This is in contrast to some, even recent, reports of postradiation pain and tenderness. We agree with Leddy and Johnson² of the Mayo Clinic that such reactions are probably due to careless shielding, with inclusion of some normal skin.

With the stubborn, previously treated warts we have encountered, usually three and sometimes four such intensive and four-fifths doses are required. Gradually it is noticed that the papillary lines, which in the untreated wart are widely swung around or end abruptly at its margin, assume their normal arrangement. In the end they cover the site. At the same time the surrounding callus becomes thinner, and, finally, it assumes the thickness of the other parts of the tread. There have never followed any indications of atrophy or of radiodermatitis. We have examined feet so treated many years after

Fig 1

Fig 1 Mosaic type of Verruca plantaris showing aggregate warty cores in patches which are impossible to shield closely These are radioresistant

Fig 2

Fig 2 Mosaic wart shaved down to show individual cores

we have found to be amenable to suggestion therapy in its varied forms and subterfuges (Fig 5)

In the so-called "mother-daughter" type, which may involve any part of the sole, there is a central larger lesion with outlying satellites, some of which may be so minute and transparent as to resemble vesicles. These, with the multiple epidemic type, are probably of filtrable virus origin. They stand distinct as to curability from the single pressure-point, painful variety in which the factor of traumatism probably enters. It is mainly with this last type that our report deals.

As indicated above we have used roentgen rays in the treatment of plantar warts among our private patients almost exclusively, modifying the technic of others with, we think, better results. Exception is made invariably in the case of compound lesions of mosaic pattern which are often associated with lesions of verruca plana juvenilis elsewhere. In general, for this type we have found, as have others, roentgen-ray therapy (with or without filters) to be futile.

Years ago when we were using roentgen doses of 1 to 1½ skin units at monthly intervals, as recommended conservatively by MacKee,⁹ we were disappointed so often at finding no evidence of desiccation or contraction of a wart that after two or three such exposures we changed to some other form of therapy.

In the meantime better results were reported by Michael,¹⁰ Hazen,¹¹ and Taussig

and Miller,¹² using two or three erythema doses.

Then we began increasing the size of the initial dosage, having in mind also Ewing's¹³ statement that "increased resistance to radiation is acquired by a tumor after successive treatments with inadequate dosage," until 4 or more skin units (1,360 r plus) were given. This had the effect of increasing the percentage of cures. But still patients returned at the end of a month with the same active capillaries on paring and with the same pain. Usually they told of relief for a week or so, after which tenderness returned and gradually increased. That the recurring pain was not due to a subwart reaction from the previous raying was proved by the fact that it ceased after the second dose and was not followed by painful puffiness.

Still believing our technic to be faulty we began giving somewhat reduced large doses at intervals of three and of two weeks. Obtaining better results we lowered the interval to ten days. This ten-day period between rayings has been maintained with few exceptions throughout the series.

The inference to be drawn from the experiments of Kingery,¹⁴ modified somewhat by other more recent measurement methods mentioned by MacKee,⁹ seems to prove that our reasoning was not faulty. Kingery deduced that the maintenance of the optimum tissue effect of roentgen rays must depend upon the rate at which the rays are lost, that the residual effect has become negligible in

astringent powder under a light cocoon dressing. And for protection from pressure a half-moon-shaped, felt pad is applied.

Comparative percentage tabulations of the results of therapy are apt to be futile unless the types treated are mentioned. For example, we feel that if roentgen-ray irradiations were limited to previously untreated plantar warts one's percentage of cures would be very high. It would be still higher if only the multiple, infective, epidemic variety in children were selected. On the other hand the opposite would hold if lesions of the mosaic patch type predominated. As mentioned, the majority of plantar warts in our series were of the limited, resistant type scarred by previous attempts at removal. Most were on weight-bearing areas. Some, but not many, resisted therapy with our technic and had to be removed by other means attended by temporary disability.

In our series there were 583 cases, in which the end results are known in 487. Of these 439 were cured by roentgen therapy alone, an average of 90.35 per cent. There were 48 failures. Twenty-nine were cured in one treatment. This is low in comparison with the reports of others and probably is due to the resistant type treated in our series. The total dose varied from 1 skin unit to 20. Eleven lesions required 15 or more skin units. The average total dosage was 6.86 units. The average number of treatments was 3.28. Two hundred and fifty-five patients had single lesions, 328 had two or more. The average age of patients was 28.5 years. The ratio of women to men was $2\frac{1}{2}$ to 1.

There were 96 cases in which the final result is unknown. We feel confident that some of these should be placed in the class of cures by one treatment. Others undoubtedly received so much relief from the first or second raying that they thought further treatment was unnecessary.

Summary

The treatment of plantar warts exclusively by roentgen rays in a series of 583 private patients in the past eleven years is reported. Of the 487 cases in which the end results are known, 439 or 90.35 per cent were cured.

Mosaic warts with ill-defined edges, which we have found to be radioresistant or unsuitable for adequate close shielding, were not included. Otherwise all the cases in the series were unselected.

Most of the lesions had resisted treatment by others using other methods or were recurrences. Many were fibrosed. Their average duration was eleven months.

A radical modification of the usual technic of roentgen therapy has been developed. Briefly, it comprises the use of a large predetermined initial dosage, its size depending upon several factors, followed at ten-day intervals by one, two, or three saturation doses, four-fifths that of the initial dose, through precisely fitting shield-holes in lead sheeting. These holes are reduced in size as the lesion shrinks.

There has been an entire absence of subwart reaction or of any unfortunate sequelae.

This technic is recommended as a standard for roentgen-ray therapy of plantar warts. It is highly effective, safe, painless, comparatively rapid, and entails no disability or loss of time.

IN CALIFORNIA, THERE THEY COME

The California Physicians Service has grown steadily in clientele by 1,000 to 1,500 members a month since its start in August, 1939, and in October, 1940, it had a membership of over 18,000, according to the J. A. M. A. Over

5,000 California physicians have enrolled under the plan. Collections from beneficiary members up to August, 1940, totaled \$27,409. Several schools and relief authorities are negotiating with the service for medical care.

FIG 5 Epidemic type of verruca plantaris cured by psychotherapy (by insertion of a sterile needle in the buttock)

Our patients are treated in the prone position with the sole upward and nearly horizontal. The feet rest upon a frame of light construction which we have devised. It has soft leather pads suspended on two sides. By changing its position elevations of 7 and 10 inches above the treatment table are obtained.

Patients' lead shields are preserved in their case history charts. With the holes dated they show graphically the shrinkage between treatments.

Unless two or three warts are close together, on the same plane, each wart is rayed separately. Attempts to transfer outlines of many inked-in warts by tracing paper to lead sheeting make for inexactness and the raying of some normal skin at the edges of some lesions.

In the case of the "mother-daughter" type, the older wart is given a closely shielded subintensive dose. This is followed by a dose of 1 skin unit to the whole warty area through a large common shield-hole. Usually later on the satellites are found to be darkening and desiccating, requiring no more irradiation. The large lesion is treated thereafter, if necessary, by the usual ten-day, four-fifths dosage.

Seldom have we broken our rule never to irradiate a wart previously treated by others with radium or roentgen rays. For, even if the total dosage given is known, one can never be quite sure as to the size of the aperture through which the irradiations had been given. Some patients have come to us with definite radiodermatitis about a lesion. One such patient presented a wart under a middle metatarsal head. A circle of radiodermatitis caused by raying a wart in the same location

years before involved even the tips of some toes. Recently, a woman was referred to us for further irradiation of a lesion under a pressure point. Under a moleskin disk the wart was encircled by an inked-in oval extending in one direction $\frac{1}{4}$ inch beyond its margin.

Our initial dosages have been increased gradually until in some rare instances they approach those mentioned by Osborne and Putnam,¹ who give up to 8 skin units and repeat once in two months if necessary. Following their report in 1931 we tried this one-large-dose method in several cases, but there were too many failures. The fact that conservatism has governed all our exposures is proved by the absence of sequelae. We have had occasion to see many of our wart patients years afterward for other dermatologic conditions. Invariably an examination of the feet is made, and invariably it is impossible to find the site of the lesion rayed, unless there had been scarring from treatment antedating ours.

The size of the initial dose has to be determined for each wart, depending on its size, depth, vascularity, amount of keratinization, and the amount of fibrosis from previous types of treatment. The horny tissue left after paring acts as a filter. Andrews¹¹ states that it has an absorption coefficient equivalent to aluminum. In general it is safe to work on the rule that the larger the lesion the smaller the dose. Excepting mosaic patches, one seldom sees a plantar wart of over $\frac{1}{2}$ inch in diameter. An initial dose of 3 to 4 skin units can be given it safely. To a lesion $\frac{1}{4}$ inch in diameter a dose of 4 to 5 units is effective and safe with close shielding. A markedly keratinized lesion may require more. A vascular lesion with radiating papillae, a wart at its acme before the regressive stage when mitosis ceases, will respond to a smaller dose.

As a rule children require smaller doses. Their limited lesions are not so keratinized or so deep. It is safer also to employ reduced doses in patients with diabetes, in those with trophic disturbances (e.g., from neurosyphilis), and in those with faulty peripheral circulation. But it must be stressed that in these conditions roentgen therapy is by far the safest method to employ.

We remove all hand and other warts by electrocoagulation to prevent recurrences from potential foci.

Between our plantar wart treatments we endeavor to keep the lesion dry by use of an

is by way of the blood vessels in the marrow spaces between the outer and inner tables of the skull with ultimate necrosis of the compact bone of these tables, the formation of "Pott's puffy tumors," extradural abscess, frontal lobe abscess (which is very common and of surprisingly early formation), meningitis, and death. The upper limit of the edema is a close approximation to the progress of the bone infection, but the characteristic mottled appearance, when seen in an x-ray plate, is usually about ten days behind the extent of the infection. While in some cases the osteomyelitic process is relatively benign, tending to self-limitation and the formation of sequestrums which can easily be removed, as a rule the disease is steadily progressive, and the careful surgeon will not delay once his diagnosis is established but will with apparent ruthlessness remove all diseased bone of both tables as well as a 2-inch margin of healthy bone. This leaves an appalling defect in the protective skull—frontal, parietal, temporal, or whatever cranial bones have been involved—but, fortunately, in many instances osteogenesis takes place with the formation of a new protective cranial plate. Much can be done to help accomplish this result, but further discussion is beyond the limits assigned to this presentation.

In connection with head pain it is necessary to recall that suppurative diseases of the middle ear, due to invasion of this space by microorganisms, will produce pain centering in the ear and mastoid and which is usually very great in the acute states. Politzer classically describes it as follows: "Purulent inflammation of the middle ear begins with piercing, tearing, boring, throbbing pains in the ear, which radiate towards the vertex, occiput, teeth and shoulder." Not all cases present this description, but the proper management of an acute suppurative otitis media based upon a good history and an accurate interpretation of the otoscopic picture will prevent, in many cases, the development of deeper involvement with such serious sequelae as to lead to a fatal issue. A well-performed myringotomy at the proper time is one of the most valuable otologic procedures.

The question of unexplained fever in infants and children comes up frequently in the general practice of medicine. Often after the most painstaking study, the cause of the fever still remains unexplained. A myringotomy in these cases may cause a prompt defervescence. It is well to recall that the lymphatics of the middle ear of the infant or child are nine

times more permeable than those of the adult and, therefore, constitute a greater degree of absorption, as pointed out by W S Bryant.

Many infants have shown protracted gastrointestinal disturbances (diarrhea, dehydration, athrepsia, malnutrition), and careful studies conducted by Dean, Lyman, Jeans, Marriott, Byfield, and others pointed to a possible relationship between middle-ear infection and the intestinal symptoms. Myringotomy for the purpose of obtaining ample drainage from the middle ear and, where the symptoms persisted, an antrotomy or a formal mastoidectomy often produced favorable results.

Unexplained fever in infants and children should always direct attention to the ears and accessory sinuses, especially if the individual presents evidence of athrepsia or malnutrition that does not yield to standard pediatric measures. In such cases a frank, middle-ear suppuration or mastoiditis is rarely found, and at times the decision to operate (myringotomy or antrotomy) must rest largely on the fever, weight, and diarrhea chart.

General malaise, loss of weight, cough, and mild evening fever may be due to an almost symptomless infection of the paranasal sinuses, especially in children, and the diagnosis is made only after careful clinical and x-ray study, after suspicion has been directed to this region, or after other measures of control have failed. The usual symptoms are frequent nasal colds, more especially post-nasal discharge, often overlooked, and the appearance of chronic, inflammatory signs in the nasal mucosa and by x-ray studies. It is surprising how often an apparently intractable case of bronchitis or early bronchiectasis in children will promptly yield to conservative measures directed toward control of sinus infection.

I will not attempt to detail the symptoms and signs of a typical mastoiditis, since they are, doubtless, well known to all of you. It should be remembered, however, that a large number of cases of acute mastoid infection do not present all, or at times many, of these diagnostic signs and that even the x-ray is not infallible. For instance, we may have this pathologic condition without fever, pain, tenderness, edema, or even otoscopic evidence of middle-ear infection. A seventh nerve or facial paralysis in a case of acute middle-ear infection may be directly due to this cause without any more mastoid inflammation than is always present in acute otitis media, but it must be remembered that herpes zoster ota-

EARLY RECOGNITION OF SERIOUS LESIONS OF NOSE, THROAT, AND EAR

GEORGE MORRISON COATES, M D , F A C S , Philadelphia

YOUR secretary, in assigning to me this title, asked that I deal with the consideration of some of the more common symptoms found in the upper respiratory tract, which, when carefully observed and studied, might disclose, in some instances, serious lesions either in neighboring or remote parts. With the view to preventing unforeseen or untoward pathologic sequelae, I shall briefly set forth a number of symptoms, with comments, which I hope will fulfill the plan of this presentation.

Headache is a symptom that every doctor is confronted with in his practice. It is fully appreciated that one or more systems, other than the upper respiratory tract, may or may not be the absolute direct cause. Nevertheless, certain principles should be borne in mind with regard to the respiratory system. Sinusitis may be present even though the patient gives no history of headache. When headache is present, inquiries relative to the character of the pain—situation, duration, frequency, exacerbations, and remissions—are of the utmost importance, because, together with the examination and other diagnostic aids, they may throw light upon what sinuses or group of sinuses may be involved. All of us recognize, I am sure, the protective function of the nose. When this important function becomes impaired, the accessory sinuses, the ears, eyes, larynx, tracheobronchial tree and lungs, the bones of the skull, the brain and its coverings, important blood vessels in the interior of the skull—any of these vital structures—may become seriously involved with possible fatal consequences. Thus, a sphenothmoid or frontal sinus infection can easily lead to an osteomyelitis if the microorganisms are virulent and the bone is in a poor nutritive state. Depending upon the virulence of any of the bacteria, the resistance of the host, and the physical and other constitutional assets of the patient, if the sinuses are not dealt with adequately to allow them to recover their normal function, they may act as a focus of infection for the intracranial structures as they unfortunately often do. An ap-

preciation of the anatomy and physiology of these structures, with a good history and careful examination followed by proper therapy, conservative or operative as the situation demands, will obviate serious secondary lesions elsewhere.

Excessive nasal and postnasal discharge, as well as frequent "head colds," calls for a thorough review of the sinuses, irrigation of such sinuses as may be readily irrigated so that the washings may be evaluated, and x-ray studies, first using the flat plate and then, if necessary, radiopaque oil for the purpose of delineating thickened mucous membrane, polypi, etc. By such methods the source of pus will be found, after which such therapy as indicated can be instituted.

Where intracranial complications arise during the course of a sinusitis (or otitis media) and where meningeal symptoms, external orbital swelling, blindness, retinitis, choked disk, iridocyclitis, exophthalmos, fistulas, and the usual neurologic manifestations are present, a quick survey of the sinuses (or ear) should be made and the focal point or points of infection found and thoroughly eradicated or drained. All other measures along approved surgical lines should be carried out.

Acute infection of the nasal sinuses, especially when it is secondary to swimming and when it involves the anterior ethmoid and frontal cells, frequently causes edema of the eyelids, sometimes massive, headache, pain, fever, and nasal discharge. Such a picture is always alarming, since necrosis of the bony walls of the involved sinus may easily take place unless drainage is quickly established and complications may rapidly develop. Among such complications are orbital cellulitis and cavernous sinus thrombosis, which it closely simulates, meningitis and frontal lobe abscess, and the much dreaded osteomyelitis of the frontal bone. The latter complication sometimes follows operations on the nose, especially the frontal sinus, and, as a rule, develops slowly, sometimes even after the acute sinus symptoms have subsided. When such is the case, it is characterized by low fever and edema slowly spreading upward from the upper eyelid and eyebrow to cover, in some instances, the entire calvarium. Osteomyelitis is an infection of diploic bone, and its spread

Read by invitation at the Annual Meeting of the Medical Society of the State of New York, May 9 1940

Professor of otorhinology, Graduate School of Medicine, and emeritus professor of otolaryngology, School of Medicine, University of Pennsylvania

some form of "unlocking the petrous pyramid," as originally advocated by Eagleton, is essential if life is to be saved

Epistaxis is a frequent symptom of varied conditions. It may occur during the exanthems, in some of the anemias, during the passive congestion states of cardiovascular-renal disease, in hypertension, tuberculosis, and possibly some of the metabolic disturbances. Local conditions, such as ulceration of variable etiology, trauma, and foreign bodies, also may cause nasal bleeding. (It is especially important to remember that unilateral nasal bleeding may be an expression of nasal diphtheria, and the physician should always bear in mind the possibility of benign and malignant tumors.) If a mass is noted in one naris with a history of epistaxis and if probe palpation of that mass reveals it to be friable and bleeding very easily, suspicion of a malignant growth is in order. No hesitancy should then be made in obtaining a biopsy to see the histopathologic picture. Early diagnosis of intranasal malignancy and thorough surgical and radiologic treatment will often save life.

Bleeding from the throat means that a thorough check-up of the blood should be made and that there should be a careful inspection of the nose, nasopharynx, oropharynx, and laryngopharynx to rule out ulcerations, fibromas, or malignancies. Heart disease and hypertension should not be overlooked, nor should hemophilia and purpura hemorrhagica.

Unilateral bleeding from the nose is most frequently from Little's area on the cartilaginous septum nasi and is caused by small ulcerations that are the result of dried secretions from the anterior sinuses, traumatism, typhoid and other fevers, hemangiomas, and other so-called benign tumors such as fibromas.

Symptoms referable to the throat may suggest a simple pharyngitis or something more serious. A blood count taken routinely in a large number of patients seeking medical advice about their sore throats is apt to reveal interesting data. Thus, agranulocytosis, leukemia, or some other blood dyscrasia may be diagnosed. Occasionally, recurrent sore throats, excluding tonsillitis and ethmoiditis, may reveal by means of appropriate blood studies either a diabetes or a nephritis.

Hoarseness indicates that there is some impairment of the larynx. The true vocal cords must approximate, vibrate, and tense properly, and any condition interfering with these

functions produces hoarseness. The causes may exist within the larynx or may be due to some cause outside of the larynx. Chevalier Jackson lists fifty conditions concerned in hoarseness and adds that this list is *nearly* complete. In the general practice of medicine it is important to examine the larynx carefully in every case of hoarseness to rule out the possibility of tuberculosis, syphilis, and carcinoma or other neoplasm. It must be remembered that two or even three of these conditions may co-exist in the same patient. Appropriate blood studies, x-ray, sputum, biopsy, bronchoscopy, and re-examinations will give an accurate diagnosis. When the latter is obtained, therapy along rational lines will give the best effects. Antisyphilitic therapy, appropriate methods used in tuberculosis, and the measures used in dealing with malignancies by cooperation of the laryngologist or bronchologist and radiologist will be a great help provided the diagnosis is made early and the treatment is carried out thoroughly.

Hoarseness in the acute stage is usually due to an acute infection of the upper part of the respiratory tract, by improper use of the voice—singing during an acute "cold," shouting at a baseball game, or the inhalation of irritating gasses. When it lasts for any considerable length of time, a careful laryngeal as well as general physical examination is imperative. Besides carcinoma, syphilis, and tuberculosis, chronic hoarseness is caused by overuse of tobacco and alcohol, improper use of the voice, chronic infection of the upper part of the respiratory tract, and hypertrophy of the pharyngeal lymphoid tissue, especially at the base of the tongue—the lingual tonsil, which is the base of the Waldeyer's ring of the older anatomists.

Laryngeal conditions usually arise secondary to some lesion elsewhere. Laryngeal tuberculosis is rarely primary, almost always secondary to lung tuberculosis. The infiltrations in laryngeal tuberculosis are found mostly in the posterior portions (posterior commissure), especially the arytenoid cartilages and the interarytenoid space. Syphilis is the dry lesion and may involve one or both cords, often a punched-out ulceration. Carcinoma may manifest itself in several varieties and in various situations, but it is most frequently seen in its early and, therefore, most curable stage in the anterior half of a vocal cord, from whence, however, it may spread in any direction. A malignant mass situated only on the vocal cord is termed intrinsic cancer, and by

cus, an intracranial neoplasm, trauma or so-called idiopathic Bell's palsy may cause this symptom. Edema over the mastoid is often caused by an otitis externa (furuncle) or infection of the scalp, pain and tenderness are also caused by these, and fever may come from any one of many sources, which must be diligently sought for in other parts of the body.

Of the complications of acute mastoiditis, meningitis, and lateral or sigmoid sinus thrombophlebitis are the most common. The neurologic signs of the former are well known, and the confirmation is by spinal canal drainage with a finding of increased pressure of the fluid and a chemical, cytologic, and bacterial study. Early diagnosis is of the utmost importance, as early surgery on the mastoid, free exposure of the dura, and appropriate chemotherapy (sulfanilamide, sulfapyridine, or sulfathiazole) is now producing many cures, whereas formerly the mortality was nearly 100 per cent. Even if the spinal fluid is aseptic, prompt surgical treatment in the presence of increased spinal fluid pressure and cell count is imperative in order to forestall a diffuse, suppurative, leptomeningitis. Infection of the lateral sinus may be symptomless and, therefore, undiagnosable, but this condition is usually recognized by an increase of fever over that probably caused by the mastoid infection to which this pathology is secondary, by the septic character of this fever, by the accompanying rigors, which mark the peak of temperature, by the presence of metastatic abscesses, usually late in the disease, by the onset of meningeal symptoms, and by a positive blood culture. The presence of some or all of these symptoms during the course of an acute otitis media or mastoiditis, either before or after operation, should lead to exposure and exploration of the lateral sinus, via the mastoid, with appropriate surgical drainage and, in many instances, ligation of the internal jugular vein in an effort to prevent the further spread of the infection in the general circulation where the lodging of an infected embolus in a vital organ may cause death.

A chronic running ear, particularly with a thick, foul-smelling discharge, is always a potential source of danger and deserves careful watching. If the discharge is mucoid and comes through a perforation in the anterior portion of the drum head, less attention need be paid to it since its origin is usually in the eustachian tube. If in the case of the ear with a foul-smelling discharge (and sometimes even when the ear is dry for long periods) a facial paralysis develops or there is vertigo, either

mild or severe, or if pain, headache, fever, or meningeal symptoms appear, it is reasonable to assume that necrosis or absorption of bone by a cholesteatoma has approached or invaded the labyrinth, the lateral sinus, or the middle or posterior cranial fossae. A rapid diagnostic study and appropriate surgery are indicated. The radical mastoid operation is the basic surgical procedure in such a case, but it should often be resorted to as a prophylactic measure, before complications become imminent or established, where conservative treatment has failed to produce a dry ear.

One of the complications of the acute middle-ear suppuration which has come into prominence in recent years is infection of the petrous portion of the temporal bone. If the extension of infection from the middle ear or mastoid involves the labyrinth, or internal ear, as a diffuse labyrinthitis (either serous or suppurative), the symptoms, which usually appear suddenly, are chiefly intense vertigo, nystagmus, which can easily be seen, nausea and vomiting, and sudden, profound, unilateral deafness. If the infection has proceeded from the middle ear or mastoid either by pneumatic spaces or diploic bone, depending on the anatomic structure, around the labyrinth into the apex of the petrous pyramid, other symptoms are in evidence, of which the Gradenigo triad is the best known and most striking group. Paralysis of the sixth or abducens nerve prevents the outward rotation of the eyeball on that side. Pain in the ophthalmic division of the fifth nerve comes from pressure on the gasserian ganglion and may radiate over the entire side of the head and to the teeth but is especially noted in and behind the eye. There is usually a low fever and considerable malaise. When and if perforation of the cortex takes place, the pain ceases for the time being, but soon symptoms of meningitis supervene. If the perforation occurs on the lower surface of the pyramid, the suppuration may make its appearance as a retropharyngeal abscess. Not every case presenting the symptoms mentioned above needs the extensive operative procedures designed for the relief of this condition—petrositis or apicitis, often a simple mastoidectomy, very completely done, or a revision of the mastoid wound will provide sufficient drainage to ensure recovery. In other instances a radical mastoid operation is necessary, but, if signs of meningeal invasion begin to appear or if the case does not show evidence of recovery after appropriate mastoid surgery,

isolated. Many of the streptococci are found in the secretions. The endoscopic picture in some cases shows a dry, velvety mucosa, mottled by erosions, with crusts obstructing the bronchial orifices, other cases show varying swellings with gummy pus, red, inflammatory mucosa, and no air bubbling past. These cases are profoundly toxic. Culture will differentiate them from diphtheria. Complications are the rule—blood-stream infection, endocarditis, pericarditis, and myocarditis. Often the toxemia damages the cardiac muscles to such an extent as to render them incapable of functioning and also causes an associated pulmonary condition, for these cases have elements of bronchitis and bronchopneumonia with atelectatic areas.

The treatment of this disease resolves itself into general and local measures. The pediatrician must be on the lookout for visceral complications and combat them to the uttermost. The duty of assuring an adequate airway falls to the laryngologist, and the most certain manner of accomplishing this is to have the child properly hospitalized where tracheotomy and all the necessary bronchologic procedures and technique can be carried out *in extenso*.

Edema of the larynx, though not so common as other forms of laryngitis, is not a rare disease. It is sometimes secondary to Ludwig's angina, peritonsillar and retropharyngeal abscess, allergic states, etc., and extension by continuity of tissue is the rule. Many of the commoner pyogenic cocci have been demonstrated bacteriologically. Occasionally it may occur primarily. The larynx appears as two large, round, red eminences, the mound extending all the way to the epiglottis on each side. The latter may or may not be involved but it is very red. The patient is hoarse, and the general symptom is one of an acute septic inflammation. Many complications can arise, septicemia, cardiac failure, and asphyxia being the more common ones. The disease calls for systemic treatment, adequate elimination by skin, kidney, and bowel, abundance of fruit juices and vegetables, and tracheotomy when dyspnea supervenes.

Asphyxia is defined by Chevalier Jackson as "Death for want of oxygen and carbon dioxide in the tissues." It is stated that 98 per cent of all deaths with the patient on his back, as he usually is, are by asphyxia in the terminal stage because of the check-valve action of the tongue. The "lingual check valve"¹ is often the direct cause of death.

The tongue becomes obstructive, and in a dorsally recumbent person it becomes a check valve permitting egress from, but not ingress of, air into the lungs. Such cases must be properly handled and tanks of oxygen (plus 5 per cent carbon dioxide) should be kept at all first-aid stations. When artificial respiration is given, the tongue should be pulled forward to allow free ingress of air. The pulling forward of the tongue and turning the patient on his face eliminates the lingual check valve.

Another cause of alarming dyspnea is bilateral abductor paralysis which may so interfere with respiration that a tracheotomy becomes necessary to save life. This sometimes follows thyroidectomy, either from traumatism to the recurrent laryngeal nerves during the operation or their later involvement in the resulting scar tissue, or it may be central in origin.

Tinnitus aurium is a distressing symptom often encountered in general practice. In the absence of any local ear disease, some constitutional factor is usually the cause: vascular lesions, hypertension, excessive use of coffee, tobacco, alcohol, certain drugs as quinine and salicylates, climatic and atmospheric conditions, pregnancy, gastrointestinal disturbances, and varying foci of infection. This symptom requires an investigation of the physical condition of the patient, with a check-up of the acoustic and non-acoustic labyrinth as well as foci of infection in the head and elsewhere. Elimination of such infected foci as devitalized teeth, infected tonsils, correction of nasal faults, and sinus suppuration as well as the elimination of distant foci will greatly aid many cases. If, however, the tinnitus aurium is due to some intracranial condition, no favorable results will be obtained by any measures outlined above. Often tinnitus is due to pathologic processes in the eustachian tube, middle ear, and inner ear, of which the last named is the most common cause if any ear disease at all is present. Otosclerosis comes under this heading. Many newer plans of therapy have been adopted for the treatment of this disturbing symptom. All cases of tinnitus aurium call for a complete overhauling of the economy.

Vertigo is another common symptom of variable etiology. It may be the local manifestation of a general condition, i.e., some toxic or metabolic fault either in the colon, gallbladder, teeth, and/or other loci irritating the non-acoustic labyrinth. The nonacoustic labyrinth is older than the acoustic labyrinth and is

means of surgery and radiation favorable results have been reported by bronchologists. Where the mass has extended to the structures outside the true vocal cords, it is termed extrinsic cancer. The latter condition is only operable by laryngectomy because the infiltration is widespread. It is clear, therefore, that the early diagnosis and proper management of intrinsic laryngeal cancer may save life. The laryngeal surgeons have now accumulated sufficient data and statistics to prove their results even in many cases of several years standing.

Many primary blood dyscrasias produce lesions in the nose and throat which may lead to early recognition of a serious general condition that otherwise might escape notice. A sore tongue or glossitis is common in a large percentage of cases suffering with pernicious anemia. Red patches on the dorsum, small blister-like elevations on the sides, and eventually shallow, painful ulcers of short duration but showing recurrence are characteristic enough to call for an immediate blood study, as does the smooth, glazed tongue of the later stages (W E Grove). Large blister-like lesions anywhere on the mucosa of the pharynx and fauces suggest early pemphigus which is confirmed by finding similar lesions on the skin in various parts of the body. Fortunately this is a rare disease.

The appearance of necrotic and gangrenous processes in the throat and mouth, especially if accompanied by fever and prostration, suggests an acute leukemia (lymphatic, myelogenous, or monocytic) and is often accompanied by serious hemorrhages, cough, dyspnea, and adenopathies.

These lesions also occur in the chronic leukemias and are accompanied by glandular hypertrophies, especially of the tonsils, in which case disastrous results may be encountered if removal is practiced under a mistaken diagnosis. Hemorrhage into the inner and middle ear often occurs in these dyscrasias, and, even if the general disease is brought under a measure of control, irreparable damage is done to the hearing or vestibular functions. In the latter case we have the typical Ménière's syndrome. Therefore, if, in an otherwise healthy subject, sudden deafness, tinnitus aurium, and vertigo appear, a hemogram is indicated at once.

Generalized cervical adenopathy (particularly of the posterior cervical chain), small ulcerations on the pharyngeal mucosa, swelling of all lymphoid structures even suggesting peritonsillitis, malaise, fever, and headache

are the frequent or usual accompaniments of infectious mononucleosis. The appearance of the throat may be wrongfully diagnosed as due to influenza, grippe, typhoid fever, German measles, simple pharyngitis, tonsillitis, quinsy, scarlet fever, diphtheria, Vincent's angina, agranulocytosis, or many other general or local infections, and only a careful blood study can clarify the situation (Grove). So also a careful blood study is the only sure means of diagnosing granulocytopenia, when necrotic, spreading, ulcerations are encountered in the buccopharyngeal mucous membrane.

Cases of peritonsillar abscess and retropharyngeal abscess require adequate drainage at the proper time. Peritonsillar abscess, or quinsy, is caused by infected tonsils. If the collection of pus around the tonsil is not freely drained, one of several dangerous sequelae may arise. The pent-up pus may erode into one of the great vessels and cause septicemia or a violent hemorrhage. On the other hand, the resulting inflammation may extend downward and produce edema of the larynx—always a very dangerous condition. Retropharyngeal abscess is more serious than quinsy and calls for skillful incision, with mouth gag in position and without the use of any anesthetic. Use of a bistoury, properly taped, and prompt turning of the head downward immediately after incision to evacuate the septic contents are important points in the technic. The acute retropharyngeal cases must not be confused with the chronic forms that are due to caries of the cervical vertebrae and belong in the domain of the orthopedist. Patients with abscess either in the retropharynx or in the peritonsillar tissues suffer great pain and are unable to open their mouths because of the inflammation. They are virtually starving, and it is remarkable how quickly they become dehydrated and lose weight.

Acute infective laryngotracheobronchitis in children is not a very common condition but a number of cases are seen every winter in the bronchologic clinics. This condition is an acute septic inflammation of the mucosa of the larynx, trachea, and bronchi, characterized in typical cases by toxemia, edema of the larynx, and thick, viscid, obstructive, often crusting, nonmembranous exudate in the tracheobronchial tree. This disease occurs epidemically, endemically, and sporadically. It is often overlooked as a "cold." The etiology is an infection, and the disease is contagious. No specific microorganism has been

isolated. Many of the streptococci are found in the secretions. The endoscopic picture in some cases shows a dry, velvety mucosa, mottled by erosions, with crusts obstructing the bronchial orifices, other cases show varying swellings with gummy pus, red, inflammatory mucosa, and no air bubbling past. These cases are profoundly toxic. Culture will differentiate them from diphtheria. Complications are the rule—blood-stream infection, endocarditis, pericarditis, and myocarditis. Often the toxemia damages the cardiac muscles to such an extent as to render them incapable of functioning and also causes an associated pulmonary condition, for these cases have elements of bronchitis and bronchopneumonia with atelectatic areas.

The treatment of this disease resolves itself into general and local measures. The pediatrician must be on the lookout for visceral complications and combat them to the uttermost. The duty of assuring an adequate airway falls to the laryngologist, and the most certain manner of accomplishing this is to have the child properly hospitalized where tracheotomy and all the necessary bronchologic procedures and technic can be carried out *in extenso*.

Edema of the larynx, though not so common as other forms of laryngitis, is not a rare disease. It is sometimes secondary to Ludwig's angina, peritonsillar and retropharyngeal abscess, allergic states, etc., and extension by continuity of tissue is the rule. Many of the commoner pyogenic cocci have been demonstrated bacteriologically. Occasionally it may occur primarily. The larynx appears as two large, round, red eminences, the mound extending all the way to the epiglottis on each side. The latter may or may not be involved but it is very red. The patient is hoarse, and the general symptom is one of an acute septic inflammation. Many complications can arise, septicemia, cardiac failure, and asphyxia being the more common ones. The disease calls for systemic treatment, adequate elimination by skin, kidney, and bowel, abundance of fruit juices and vegetables, and tracheotomy when dyspnea supervenes.

Asphyxia is defined by Chevalier Jackson as "Death for want of oxygen and carbon dioxide in the tissues." It is stated that 98 per cent of all deaths with the patient on his back, as he usually is, are by asphyxia in the terminal stage because of the check-valve action of the tongue. The "lingual check valve" is often the direct cause of death.

The tongue becomes obstructive, and in a dorsally recumbent person it becomes a check valve permitting egress from, but not ingress of, air into the lungs. Such cases must be properly handled and tanks of oxygen (plus 5 per cent carbon dioxide) should be kept at all first-aid stations. When artificial respiration is given, the tongue should be pulled forward to allow free ingress of air. The pulling forward of the tongue and turning the patient on his face eliminates the lingual check valve.

Another cause of alarming dyspnea is bilateral abductor paralysis which may so interfere with respiration that a tracheotomy becomes necessary to save life. This sometimes follows thyroidectomy, either from traumatism to the recurrent laryngeal nerves during the operation or their later involvement in the resulting scar tissue, or it may be central in origin.

Tinnitus aurium is a distressing symptom often encountered in general practice. In the absence of any local ear disease, some constitutional factor is usually the cause: vascular lesions, hypertension, excessive use of coffee, tobacco, alcohol, certain drugs as quinine and salicylates, climatic and atmospheric conditions, pregnancy, gastrointestinal disturbances, and varying foci of infection. This symptom requires an investigation of the physical condition of the patient, with a check-up of the acoustic and non-acoustic labyrinth as well as foci of infection in the head and elsewhere. Elimination of such infected foci as devitalized teeth, infected tonsils, correction of nasal faults, and sinus suppuration as well as the elimination of distant foci will greatly aid many cases. If, however, the tinnitus aurium is due to some intracranial condition, no favorable results will be obtained by any measures outlined above. Often tinnitus is due to pathologic processes in the eustachian tube, middle ear, and inner ear, of which the last named is the most common cause if any ear disease at all is present. Otosclerosis comes under this heading. Many newer plans of therapy have been adopted for the treatment of this disturbing symptom. All cases of tinnitus aurium call for a complete overhauling of the economy.

Vertigo is another common symptom of variable etiology. It may be the local manifestation of a general condition, i.e., some toxic or metabolic fault either in the colon, gallbladder, teeth, and/or other loci irritating the non-acoustic labyrinth. The nonacoustic labyrinth is older than the acoustic labyrinth and is

more resistant to irritating influences than the latter. Nevertheless, many toxic conditions may exist in the body which could conceivably irritate this structure. Any space-taking lesion in the brain may, by pressure, interfere with the normal function of this finely balanced mechanism whose function is motion sensing and equilibrium.

When confronted with a case of vertigo, it is important to check the ear by appropriate tests, such as voice, whisper, tuning forks, and audiometer, in order to analyze the acoustic efficiency and then to conduct vestibular tests, both by the turning chair and douching the ear with cold water at 68 F. The purpose of these vestibular tests, often referred to as the Bárány tests, is to elicit certain normal or abnormal reactions by stimulating the semicircular canals of the internal ear.

The vestibular (Bárány) tests are valuable in the diagnosis and localization of lesions of the inner ear and in many instances have been a tremendous aid in localizing intracranial lesions where other methods were without success. Differential lesions of the intracranial structures can often be brought to light by this means, as has been shown by Jones, Shuster, and many others who have also stressed the fact that these tests must be considered as only one link in the diagnostic chain of studies. Functional impairment of the ear may be an expression of a space-taking lesion in the brain or of toxic, metabolic fault, all of which should be thoroughly investigated.

Unilateral deafness not due to traumatism, leukemia, or middle-ear infection is most frequently due to (1) otosclerosis, a constitutional condition of unknown etiology, accompanied by tinnitus aurium and, frequently, by vertigo, eventually becoming bilateral and of approximately equal degree in each ear, and rarely progressing to total loss of hearing function, (2) acoustic neuromas, of which it is often the earliest recognized sign, leading to total deafness and extinction of the entire vestibular function on the involved side and loss of reactivity in the vertical semicircular canals on the contralateral side—tumors in the cerebellopontile angle, therefore, are frequently accompanied by vertigo and, in the later stages, by other neurologic signs of a space-taking intracranial lesion, (3) a neoplastic growth, benign or malignant, in the lateral wall of the epipharynx, filling Rosenmüller's fossa and occluding the pharyngeal orifice of the eustachian tube on one side.

Cavernous sinus thrombophlebitis is still the most deadly complication faced by the otolaryngologist. It is, at times, secondary to lateral sinus infection through the petrosal sinuses, but more frequently it follows acute infection of the paranasal sinuses and still more often apparently trivial skin suppurations in the butterfly area—the region of the upper lip, cheeks, and nasal tip. The symptoms are definite and striking: headache, edema of one or both eyelids, chemosis and massive edema of the orbital conjunctiva, proptosis and fixation of the eyeball, rapid spread of all these signs to the opposite side, symptoms of meningitis or septicemia, chill and a septic type of fever, bacteremia, and death in the vast majority of cases. Unfortunately, once the disease is sufficiently established to give signs and symptoms, recovery is rarely obtainable, but prophylaxis should be practiced in all cases of small suppurations in the front of the face. Furuncles should be treated with great respect and never should be squeezed or incised until a definite area of necrosis appears and then only deeply enough to give vent to the purulent secretion. The practice of pulling hairs from the nasal vestibule is utterly to be condemned.

Conclusions

The early recognition of serious lesions of the nose, throat, and ear can only be obtained by appreciating the anatomic relationship of the nose, accessory sinuses, and ear to the intracranial structures, especially the intimate blood and lymph vascular nutritional supply with tributaries connecting all of these important structures almost as one unit, thus explaining the pathway of infection from one locus to another, bearing the cardinal principle in mind that "inflammation no matter where, is always the same" (Ravdin). Fortunately, physiology (function) also enters into all living processes which, by the infinite principles contained in this cornerstone of medicine, cause numerous modifications. Otherwise, every sinus or ear suppuration would immediately involve the brain, which happily is not the case. Malignancies, to be dealt with properly, must be recognized early. Finally, the normal functioning of the upper part of the respiratory tract will go far in preventing serious lesions of the nose, throat, and ear, with resultant involvement of the eyes, lungs, brain and its coverings, and other loci *minores resistentiae*.

CLINICAL EXPERIENCES WITH STILBESTROL

A. R. ABARBANEL, M D, and MILTON D. KLEIN, M D, New York City

ALL biologic processes are essentially chemical in nature. The clarification of this fundamental concept is proceeding slowly but surely to a wider and more significant understanding of our body economy. In no field have the advances been more brilliant than those being made in the realm of sexual physiology. On the basis of the pioneer research of Windaus and others on the skeletal structure and chemical properties of the sterols, biochemists have isolated, determined the chemical structure of, and partially synthesized estrone, testosterone, progesterone, desoxycorticosterone, and a host of their derivatives. To this particular group of compounds the general term of steroids has been applied.

Struck by the close structural relationship between estrone and the phenanthrene group of carcinogens, Dodds and his co-workers soon found that the latter group were also weakly estrogenic (Fig. 1). The search for a more potent estrogenic substance led this school to a study of p-anol. At first, Dodds and his co-workers believed that this substance was the long-sought desideratum of their modern alchemy. Further study, however, soon revealed that the very potent action of p-anol was in reality due to a contaminant. In a very short time these brilliant chemists isolated and synthesized a new group of compounds possessing marked estrogenic activity.¹

Among the most potent of these was diethyl-dihydrovystilbene, most commonly known as stilbestrol. In the short space of two years since the preliminary report of the isolation of stilbestrol, an extensive literature, both experimental and clinical, has confirmed the original findings of Dodds and his co-workers that stilbestrol not only duplicates practically every action of the naturally occurring estrone but that it is a more potent estrogen weight for weight. Moreover, stilbestrol retains almost all its potency when administered orally.¹ The consensus of these reports is now widely known.

This report is concerned with the effects of stilbestrol upon the initiation and maintenance

of lactation, in preventing and relieving painful engorgement of the breasts in the puerperal patient, as a "priming" agent for the induction of labor in the pregnant patient, and as an adjuvant in the management of the patient with a menopausal syndrome. Its use in the treatment of senile vulvovaginitis as well as in the management of gonorrheal vulvovaginitis in children is briefly discussed.

1 Lactation

Lactation may be defined as the secretion of milk by the mammary gland. The physiologic processes involved are essentially endocrine in nature. The development of the lobule-alveolar system of the glands of the breasts proceeds under the influence of the ovarian hormones.² Their effects are more marked during pregnancy. After parturition, the initiation of the process of secretion of milk by the mammary gland is directly dependent upon the presence of the anterior lobe of the pituitary, for hypophysectomy during late pregnancy will prevent milk secretion post-partum.³ The anterior pituitary is also essential for the maintenance of established lactation, for removal of the hypophysis at this time will result in a rapid and complete cessation of milk secretion.⁴

While the initiation of lactation appears to proceed under purely hormonal influences the maintenance of established lactation requires, in addition to the hormonal factors, a neurogenic one. This is the act of suckling, which reflexly stimulates the release of lactogenic principle by the anterior pituitary.⁴ In this manner the continued secretion of milk is maintained.

Clearly, then, the process of lactation resolves itself into two fundamental mechanisms—first, the initiation of lactation by hormonal factors and, second, the maintenance of established lactation by both hormonal and neurogenic agencies.

Failure to differentiate clearly these two basic principles may account for much of the apparently contradictory experimental evidence. The latter has been adequately reviewed recently by Turner.⁵ In brief, experimental evidence for the inhibition of the onset of milk secretion and suppression of established lactation by estrogens is still far from decisive.

Presented by Dr. A. R. Abarbanel before the Section of Obstetrics and Gynecology, The New York Academy of Medicine, New York City, February 27, 1940.

From the Department of Obstetrics and Gynecology, Morrisania Hospital, New York City (Dr. H. Aronow, director).

FIG 1 The structural formulas of the natural estrogen, estradiol, the phenanthrene nucleus of certain carcinogens, p-anol and the synthetic estrogen diethylidihydroxystilbene most commonly known as stilbestrol

In spite of the inconclusive experimental evidence, many clinical reports have appeared claiming inhibition or suppression of lactation in the human with estrogens, including stilbestrol. Orally, the dosage has ranged from 3 mg of estrone⁶ to 60 mg of stilbestrol.⁷ Intramuscularly, doses up to 25 mg of estradiol benzoate have been used.⁸ Unfortunately, these reports cannot be properly evaluated, for the baby was removed from the breast simultaneously with the administration of the estrogen, and it is a well-known fact that the maintenance of lactation is dependent upon the nervous stimulus of suckling or its equivalent.

In view of the unconvincing experimental evidence and clinical data, it was decided to investigate the effect of estrogens upon lactation in the human. The estrogen chosen was stilbestrol, since it retains almost all its potency on oral administration while its administration requires a minimum of nursing care. This study was divided into three parts.

I The effect of stilbestrol upon established lactation in the nursing mother was investigated first. For this purpose a group of 50 mothers whose babies were normal in every respect and who gave a history of having adequately nursed a previous child for at least three months were chosen. The babies were allowed to nurse for twenty minutes five times a day. The daily amount of mother's milk was computed from *ante cibum* and *post cibum* weighings. Half the group served as

controls. Stilbestrol, in dosages ranging from 50 to 500 mg, was administered orally over a course of one to four days after lactation had been adequately established for twenty-four to seventy-two hours. Briefly summarized, the results obtained demonstrated no apparent suppression of lactation as judged by the baby's daily weight as well as the total amount of milk secreted daily. Clearly, then, the estrogen, stilbestrol, does not affect established lactation in the nursing human being.

II The effect of stilbestrol upon the initiation of the secretion of milk in the nursing human being was then studied. Using the same control group of 25 mothers and babies as in the first experiment, another group of 25 was selected using the same criteria. Beginning soon after parturition, this test group received from 50 to 1,000 mg of stilbestrol orally, in divided cases, over the course of the first three to ten postpartum days. The babies were allowed to nurse as usual.

Briefly stated, it was found that the onset of lactation on the third or fourth day postpartum was not prevented. It was noted, however, especially when the dosage exceeded 200 mg of stilbestrol that the average normal range of 7½ to 14 ounces of mother's milk daily was not reached until two to seven days after the last dose of stilbestrol, depending upon the total dosage. In every case, however, lactation was adequately established, provided the baby continued to nurse, soon after the stilbestrol was discontinued.

Evidently, then, the estrogen, stilbestrol, does not inhibit the onset of lactation, although in adequate dosage it will delay the appearance of the normal average amount of milk secretion in the nursing human being for two to seven days after the last dose of stilbestrol.

III The next question to be answered, then, was this: since estrogens neither suppress nor inhibit lactation if the baby nurses, will they prevent or relieve painful engorgement of the breasts if the baby does not nurse?

A third group of 65 full-term patients was then chosen. In 55 the indication for not nursing was present at the time of delivery. (It was thought advisable not to include post-abort cases in this series since in the vast majority the degree of painful engorgement, if any, was mild, and the amount of milk secretion, if any, was slight and transitory.) Fluids were not restricted, while in some cases they were purposely forced.

After trials of varying dosages it was found that the most consistent results were secured with the following schedule. Five mil-

grams of stilbestrol were given twice the first day and then one 5-mg tablet each day for three or four days. The same dosage was continued for five or six days in multiparas who gave a history of having lactated well before. The total dosage, therefore, ranged from 25 to 40 mg.

Twenty of these 55 patients showed some slight transitory heaviness or filling of the breasts anywhere from the fifth to the eleventh postpartum day. This engorgement, as a rule, was practically painless and merely consisted of some slight heaviness of the breasts with an occasional transient secretion of milky fluid. These patients were usually relieved by merely using a moderately loose, uplift breast binder.

In this group painful engorgement was prevented in 48 cases or 87.3 per cent, even though some painless filling of the breasts appeared in 20 or 36.3 per cent. Poor results were obtained in 7 cases or 12.7 per cent.

Of this third group of 65 patients, there was 10 women in whom established lactation had to be interrupted for various reasons. Stilbestrol was given only to those patients who had been lactating well up to the time interruption was necessary. For example, a patient with fissured nipples caused by the baby suckling on a poorly lactating breast was obviously not given hormonal therapy.

The following dosage was used. Twenty-five milligrams of stilbestrol was given as an immediate single dose. Ten milligrams was given the next day, and then 5 mg each day for three days making a total of 50 mg. Marked relief was apparent in 9 (90 per cent) at the end of eighteen to twenty-four hours.

The reason for the apparently confusing clinical reports on the effect of estrogens upon lactation now becomes evident. No attempt had been made to differentiate painful engorgement of the breast from the process of the maturation of milk secretion. Painful engorgement of the breast is not caused by distention of the ducts with milk. Painful engorgement is brought about by vascular and lymphatic stasis.⁹

2 Induction of Labor

Because of various indications, most particularly toxemias and postmaturity, it is often desirable to induce labor. In approximately 95 per cent of the cases a Watson induction (castor oil, hot enema, quinine, and pituitrin) yields satisfactory results. The management of the small group of failures (5 per cent), however, constitutes one of the greatest obstetric problems.

The now classic work of Reynolds¹⁰ and others has amply demonstrated that normal uterine contractility is primarily dependent upon estrogens. Since stilbestrol is such an active estrogen, it was used in the induction of labor. Cases were deliberately chosen from that small group of patients who failed to respond to one or more Watson inductions given at intervals of forty-eight hours.

The following case is illustrative of our approach.

M B, white primigravida, aged 36, was admitted seventeen days before term because of a mild albuminuria and a rise in blood pressure. In addition she had a prominent and rigid coccyx, while it was felt that her baby was large. Moreover, x-ray pelvimetry indicated a narrowed midpelvis. Accordingly, she received a full Watson induction during the course of which the membranes ruptured spontaneously. She failed to go into labor. Forty-eight hours later a second Watson induction was given and again she failed to go into labor. Two days later, she received 10 mg of stilbestrol orally every hour for ten doses, making a total of 100 mg. This was followed an hour later by the routine Watson induction. After the first dose of pituitrin, she went into strong active labor. In ten hours she was fully dilated, labor was terminated by a midforceps delivery because of midpelvic arrest of over three hours. The baby weighed 3,715 Gm (8 pounds 2 ounces).

In similar cases where stilbestrol was used in dosages of 100 to 200 mg only as an agent for priming the uterus to such oxytocics as quinine and pituitrin, there was an excellent response in 80 per cent of the patients treated to date, labor having been effected in four to twelve hours in practically all the successful cases. The result has been unsuccessful where stilbestrol was used alone without oxytocics, except in cases of secondary uterine inertia.

It is readily admitted that the evidence here is only strongly suggestive and is far from conclusive. Clinically, however, the results have been encouraging enough to warrant further investigation.

3 The Management of the Menopausal Patient with Particular Reference to Stilbestrol

The menopausal syndrome may occur during or after the transition period at which the reproductive function ceases. This phenomenon is a normal physiologic one, characteristic of the process of ageing. In some individuals marked vasomotor instability results. For the purpose of this report, we have taken as our criteria only the characteristic hot flushes.

FIG 1 The structural formulas of the natural estrogen, estradiol, the phenanthrene nucleus of certain carcinogens, p-anol and the synthetic estrogen diethyldihydroxystilbene most commonly known as stilbestrol

In spite of the inconclusive experimental evidence, many clinical reports have appeared claiming inhibition or suppression of lactation in the human with estrogens, including stilbestrol. The result has been unsuccessful where stilbestrol was used alone without oxytocics, except in cases of secondary uterine inertia.

It is readily admitted that the evidence here is only strongly suggestive and is far from conclusive. Clinically, however, the results have been encouraging enough to warrant further investigation.

3 The Management of the Menopausal Patient with Particular Reference to Stilbestrol

The menopausal syndrome may occur during or after the transition period at which the reproductive function ceases. This phenomenon is a normal physiologic one, characteristic of the process of ageing. In some individuals marked vasomotor instability results. For the purpose of this report, we have taken as our criteria only the characteristic hot flushes.

FIG 2 The apparatus used in making pellets is shown at A (the mold) and B (the compressor). At C is shown a 8.5 mg pellet of stilbestrol which is to be placed in the No. 12 needle, E. The needle is then inserted subcutaneously over the lateral aspect of the thigh after first making a wheal in the skin with local anesthetic. The pellet is then deposited in the subcutaneous tissue by plunging the trocar, D, home. It is to be noted that the trocar is slightly longer than the needle.

Very important, indeed, in the management of the menopausal patient is the correct diagnosis. This is frequently rather difficult, and as a result one may be forced to judge the correctness of the diagnosis by the response to therapy. Since it is a well-known fact that the vasomotor phenomena of the menopause are very greatly influenced by the patient's own psyche, one must delve not only into the patient's medical history but also into her social and economic problems in order to evaluate the patient as a whole, *not* as a diagnosis.

When the conclusion is tentatively made that the patient is suffering from a true menopausal syndrome, the following plan of therapy is instituted in the "menopause" clinic. Most important, we believe, is the axiom that each patient must be completely individualized. After securing a detailed history, the patient and her story are carefully evaluated. Therapy can be successful only if we treat the patient with the menopausal syndrome and not the menopause.

Her condition is carefully explained to her. Her complete confidence and cooperation are sought. A simple, sane, hygienic regimen, mental as well as physical, is suggested. In addition, she is given adequate sedation, barbiturates or bromides, and whatever other medication may be deemed necessary. If, after a fair trial of two to four weeks on this therapy, the vasomotor symptoms still persist in unabated form, hormonal therapy is instituted. As a result of this procedure only about 35 per cent of the patients have re-

quired the use of stilbestrol. This series comprised 75 cases treated with stilbestrol.

Two methods of administration have been utilized. These are the oral route and the subcutaneous injection of pellets of crystalline stilbestrol. Experience has shown that small doses of stilbestrol are quite effectual in controlling the hot flushes. The patient is given a 0.1-mg tablet two or three times a day. As a general rule this dosage has been sufficient. If necessary the dose is gradually increased to 1 mg a day, rarely more. If the patient gives a history suggestive of gall bladder disease, constipation, or a tendency to nausea or vomiting, $1\frac{1}{2}$ grains (100 mg) of a bile acid, desoxycholic acid, have been prescribed with each dose. When the criteria mentioned above are used, therapeutic results have been uniformly good. It is felt that this is so because the patient as a whole, not the menopause, has been treated.

In a small series of cases, pellets of crystalline stilbestrol have been injected under the skin of the thigh. The following indications for the use of pellets have been set forth. First, it must be shown that the patient will respond to stilbestrol. Second, she must experience a return of symptoms after therapy has been discontinued. Experience has shown that pellets give the smoothest and by far the best response. In addition, there is but one injection. The usual dosage employed has been pellets totaling approximately 15 mg. These remain effective for a period of two to three months. The pellet is placed in a No. 12 needle and then injected under the skin of the lateral aspect of the thigh, after first making a small wheal in the skin with a local anesthetic. The trocar, which is slightly longer than the needle, is then pushed home, forcing the pellet out. The needle is then withdrawn (Fig. 2).

Untoward reactions to stilbestrol have been uncommon. In fact, the drug has never been discontinued in any patient primarily on the basis of so-called "toxic" effects. This may be attributed to the proper selection and management of the cases. Nausea or some feeling of gastrointestinal distress was noted in about 13 per cent of the cases. The higher the initial dosage, the more frequent were the complaints. Accordingly, the patient was started out on 0.1 mg a day, and the dosage was gradually increased up to 1 mg daily if symptoms warranted it. In rare instances the dose had to be raised to 5 mg for a short period of time in order to control the hot flushes. As a result of this schedule of dosage,

Fig 3a

Fig 3b

Fig 3a Section through biopsy of vagina, from a case of pruritis associated with senile (atrophic) vaginitis

Fig 3b Fourteen days later Response of vaginal epithelium to stilbestrol ointment containing 20 mg per ounce Pruritis was markedly relieved

nausea has become a very infrequent complaint, occurring in but 4 per cent. It is insisted that the patient have a bowel movement daily. The use of bile salts or acid preparations has been found to be particularly useful in preventing or so allaying gastrointestinal complaints that the latter become insignificant.

Patients suffering from menopausal syndrome are quite prone to gastric upsets. Many will volunteer the information that they frequently feel nauseous after a particularly severe flush. Recently 2 cases of nausea and vomiting from tablets of phenobarbital and 1 from elixir of triple bromides were seen in a single week. One patient complained of nausea and vomiting after taking two 0.1-mg tablets of stilbestrol. She, however, became nauseous and vomited placebo tablets which were identical in appearance to the ones containing stilbestrol. Two of our cases complained of nausea and vomiting before therapy with stilbestrol was started. Concomitant with relief from their vasomotor symptoms, the gastrointestinal complaints disappeared. It is interesting to note that large doses of the naturally occurring estro-

gens have been noted not infrequently to cause nausea and even vomiting^{11,12}.

Uterine bleeding as a result of stilbestrol therapy occurred in about 10 per cent. This was particularly evident when the daily dose was 1 mg or more. It generally occurred when the time interval between doses was being increased or the daily dosage was being decreased. It also occurred in 1 patient who had received a large amount of stilbestrol percutaneously for kraurosis vulvae. This type of bleeding is similar to estrin-privea bleeding in the monkey. One case of apparently true "menopausal migraine" was successfully relieved.

There were no other so-called "toxic" reactions noted in this carefully studied group of 75 patients.

Senile Vulvovaginitis

In those patients complaining of pruritis vulvae, all local and constitutional causes for the irritation were first excluded. In particular, diabetes mellitus and such functional disorders of the bladder associated with incontinence of urine as a marked cystocele were ruled out. Palliative treatment with

mild antipruritic ointments was first tried. If, however, the itching was not relieved, hormonal treatment was started. By far the smoothest, quickest, and best response was secured with the use of the percutaneous route of administration. An ointment base of hydrous lanolin containing 10 to 20 mg of stilbestrol per ounce was prescribed. In cases of simple senile vaginitis the therapeutic response was uniformly excellent (Figs 3a and 3b).

Gonorrheal Vulvovaginitis—In treating this condition in children, stilbestrol proved as efficacious as the natural estrogens, both in the form of local suppositories and when administered orally. The dose in either case was 0.1 mg. The oral route seems the one of choice, since the children readily take the "pink" candy pills, whereas the mother usually has to struggle to insert the vaginal suppository. Similar results have been reported by Karnaky.¹¹

Comment

There still remains to be explained why the pregnant and puerperal patient can tolerate dosages of stilbestrol ranging from 250 mg a day to 1,500 mg a week with scarcely any side effect except occasional dizziness,¹² while the menopausal patient appears to be sensitive to doses of 5 mg a day. Perhaps some metabolic factor is altered at the time of the menopause. Study along these lines is now in progress.

The significance of the fact that stilbestrol is not inactivated by the liver¹³ has not been duly appreciated. Moreover, it has been shown that it takes from five to ten days before a given dose of stilbestrol finally disappears from the urine.¹⁴ In addition, 20 to 25 per cent of a given dose of stilbestrol may be recovered from the urine as compared to 1 to 2 per cent of estrone.^{13, 15} In other words, stilbestrol is easily capable of a cumulative action. It is logical, therefore, to use small doses. A physiologic, therapeutic effect is desired, not a pathologic one, presumably from relative overdosage.

The large percentage of so-called "toxic" effects reported by some workers¹⁶ has not been confirmed either in the clinic or private patients of our group. In fact, there have been reported more undesirable side effects with digitalis, neoarsphenamine, ammonium chloride, ferrous sulfate, and sulfapyridine, to mention but a few commonly used drugs. More discriminate selection of patients and more judicious use of proper dose schedules

in the future will bring about a decided reduction of undesirable side effects.

Summary

1 The synthetic estrogen, stilbestrol, in dosages up to 500 mg does not affect established lactation in the nursing human being.

2 Stilbestrol, if given in doses up to 1,000 mg (1 Gm) in divided doses beginning soon after parturition, will not prevent the onset of lactation in the nursing human being, although the appearance of the average normal amount of milk secretion will be delayed until two or six days after the last dose of stilbestrol, provided the baby continues to nurse.

3 Stilbestrol in doses of 25 to 40 mg prevented painful engorgement of the breasts in 87.3 per cent of 55 nonnursing mothers. A delayed transitory heaviness or filling of the breasts, usually painless, was noted in 20 of these cases anywhere from the fifth to eleventh postpartum day.

4 Stilbestrol in dosages of 100 to 200 mg acted as an excellent "priming" agent for the uterus in 80 per cent of the cases where one or more previous medical inductions of labor, including pituitrin, had been unsuccessful. Used alone, without oxytocics, stilbestrol did not precipitate labor.

5 The pregnant and puerperal patient is remarkably tolerant to stilbestrol in doses from 250 mg a day to 1,500 mg a week. No toxic effects were noted even in patients with eclampsia or fulminating toxemia and evident renal and liver damage.

6 In the management of the patient suffering from a menopausal syndrome, stilbestrol, where indicated, is an effective adjuvant in controlling the vasomotor phenomena. Beginning with 0.1 mg once or twice a day, the dosage is gradually increased if necessary. With discriminate selection of cases and judicious use of dosage schedule, uniformly gratifying results were secured. The use of bile salts or acids tended to prevent or allay untoward gastrointestinal complaints.

7 The use of pellets of crystalline stilbestrol injected under the skin of the thigh appears to offer great promise of being a most ideal form of therapy in the menopausal patient, provided the proper indications for this type of therapy are carefully observed.

8 Stilbestrol, in ointment form in a concentration of 10 to 20 mg per ounce, applied locally in patients with simple senile vaginitis associated with pruritus vulvae, yields uniformly good results.

9 Stilbestrol, in the dose of 0.1 mg per os

or in the form of vaginal suppositories, proved efficacious in the treatment of gonorrheal vulvovaginitis in children *

We wish to thank Drs Harry Aranow and Milton J Goodfriend for their valuable advice and encouragement, and to Dr S Appel we are indebted for data on the use of stilbestrol in gonorrheal vulvovaginitis. We are especially grateful for the splendid cooperation of the nursing staff in general and to the following in particular—Miss E Andes, Mrs V

* Dr J A Morrell of E R Squibb and Sons supplied stilbestrol in the form of crystals tablets and vaginal suppositories.

Mr A A Ebbey of Ayerst McKenna and Harrison, supplied stilbestrol in the form of soft gelatin capsules.

The bile preparations used were desoxycholic acid (supplied as Degalol by Riedel-de Haen) and bile salts (supplied as Crescefel by Ayerst McKenna and Harrison)

FIGHT THE GOOD FIGHT WITH ALL THY MIGHT

Congressional Intelligence, Inc., reports that a national health program of unprecedented proportions will be presented to the new Congress. In defiance of the facts, this program will be predicated on the poor health conditions alleged to have been proved by the number of rejections for military service. *Congressional Intelligence* anticipates that "with the label of defense some such program would be almost certain of Congressional approval."

Mrs Roosevelt's recent remarks lend substance to the prediction that national defense will be used as a pretext to induce Congress to adopt some form of state medicine. Actually, remarks the New York *Medical Week*, the only prevalent health needs demonstrated by Army reports to date are for better public health education, with emphasis on hygienic habits and

early recourse to medical care and more widespread utilization of available prophylactic facilities. Nevertheless, there is little doubt that those interested in socialized medicine will seize the opportunity to try and put over their pet scheme in the name of total defense.

Physicians cannot afford to wait until this danger is upon them to combat it. They must rather seek to forestall any such move by immediate contact with their representatives in Congress, letters to the press, and above all a widespread educational campaign to make the public understand the compelling reasons for medical opposition to state control. For those practitioners who have not the time nor the temperament for campaigning, the three-cents-a-day club of the National Physicians' Committee is an effective way of participating in the fight

IT'S NOT PASSION

Picked by W L A from *Chicago News*

If she calls you to her bedroom
In the hours of the night,
And thru her half closed eyelids
You detect a telltale light,
If her bosom heaves tumultuously
Betraying her devotion,
If her nostrils dilate widely
With each palpitating breath,
And her shapely body trembles as
Might one approaching death,
If she beseeches and implores you
As she grasps your trembling hand
To alleviate her suffering—the
Torture of the damned—
THAT'S ASTHMA

LECTURES ON TRAUMATIC SURGERY

A course of lectures on Traumatic Surgery has been arranged for the Fulton County Medical Society at Gloversville and Johnstown, alternately, at 9 15 P.M. The course is as follows: February 21, "The Treatment of Burns and Hand Infections," by Dr Emmett A. Dooley, February 28, "The Care of Head Injuries," by Dr Carl A. Peterson, March 7, "The Treatment of Fractures of the Femur and Humerus," by Dr Porteous Johnson, March 14, "Abdominal Injuries," by Dr David M. Goldblatt, March 21, "The Treatment of Fractures of the Forearm and Lower Leg," by Dr Walter D. Ludlum, Jr., March 28, "Bursts, Strains and Sprains," by Dr Willis W. Lasher, and April 4, "Fractures in General," by Dr Henry H. Rutter, all of New York City.

Diagnosis

THIS new JOURNAL section will carry case reports that have been made the subject of discussion from the point of view of the diagnostic process needed and the post-mortem evidence. All the cases will be selected because of some unusual interest. Two hospitals in this city have very kindly offered to supply this material, each six times a year. Reports from the New York Post-Graduate Hospital will alternate with reports from Bellevue Hospital, Fourth Medical Division.—*Editor*

CLINICOPATHOLOGICAL CONFERENCES*

FOURTH MEDICAL DIVISION OF BELLEVUE HOSPITAL

History

Patient was an 85-year-old white man, of Russian birth, a tailor by occupation, admitted with history of chills and fever of four days' duration. Ambulance surgeon obtained further history from his physician of petechial eruption that appeared and then disappeared. Present illness began nineteen days previously, patient was bitten, immediately below the left eye, on the cheek, by a rat. There was an indefinite history of other persons in the same house being bitten by rats with no subsequent symptoms. The bite was followed by considerable bleeding but in two days had healed. Four days prior to admission, patient suffered fever and chills, temperature reaching 103 F, and it was accompanied by semistupor, anorexia, but no vomiting. Past history revealed red urine for the past four months and bronchitis ten years previously.

Temperature on admission was 99 F, pulse 80, respirations, 22, and blood pressure was 120/50. Patient was very sluggish mentally but in no acute distress. Skin was dehydrated, no eruptions were present. There was a small scabbed indurated area below the left eye. Pupils of the eyes were equal and reacted to light and accommodation. There was some periorbital puffiness.

The ears, nose, and mouth were negative. Tonsillar pillars were red and injected. There was moderate swelling of the posterior cervical nodes on the left. Chest was hyperresonant and emphysematous throughout. Heart was not enlarged to percussion, sounds were distant. A soft, blowing systolic at the apex with reduplication of the second sound was present. Abdomen revealed liver to be one finger breadth below the costal margin and

not tender. No other masses or tenderness were noted. Rectal examination revealed prostate to be enlarged bilaterally with right lobe greater than left, firm and smooth—no nodules or tenderness. Extremities revealed no edema or clubbing. Reflexes were physiologic except for absent abdominals and ankle jerks.

Laboratory data included a chest plate on day of admission which showed hypervascularization throughout left lung without any definite infiltration or consolidation. Chest plate two days later showed no pneumonic consolidation. The heart was not enlarged, athermatous plaques in the knob of the aorta. Electrocardiogram on admission showed sinus rhythm, marked myocardial changes with M-shaped R waves, inverted T₁, T₂, and T₄, with slight left axis deviation.

On the day of admission the red cell count was 3,720,000, hemoglobin 80 per cent, leukocytes 11,350, of which polymorphonuclears were 85 per cent, monocytes 5 per cent, and lymphocytes 10 per cent. On the day of death red cell count 3,930,000, hemoglobin 72 per cent, leukocytes 28,900, with polymorphonuclears 83 per cent, monocytes 6 per cent, and lymphocytes 11 per cent. The urine showed a specific gravity of 1.020-1.023, there was no albumin or glucose but an occasional white blood cell. E. S. R. on the fifth day was 80 mm per hour. Blood N P N on admission was 39, on day of death was 82, blood sugar on admission was 87, blood creatinine was 2.4. Blood Wassermann was negative. CO₂ combining power was 62 per cent. Agglutination tests with typhoid (O and H), para (A and B), and melitensis were negative. The Felix-Weil reaction was negative. Blood smear on the third day was negative for malarial parasites. Injection of blood into two guinea pigs gave no reaction. Spinal fluid showed pressure to be slightly increased, protein, 37.5, sugar, 65.

Patient on admission was in no acute dis-

* The conferences are held every Thursday morning at 9:00 A. M. in the amphitheatre of the C and D building at that hospital. These sessions are included as one of the exercises in the course in postgraduate medicine given on the division under the auspices of New York University Medical College. The editorial staff for these reports consists of Dr. Charles H. Nasmack, Dr. Harry A. Solomon, Dr. Emanuel Appelbaum, and Dr. David M. Spain.

tress but was perspiring profusely and was very sluggish mentally. There was no dyspnea. Patient had a chill while being examined. Lungs were clear. Neurologic examination was essentially negative. Through the next few days the patient gradually became more stuporous. The sputum was negative for acid-fast organisms, and patient was given infusions of 5 per cent glucose in saline. Temperature rose to 101 F and varied between 102 F and 100 F, death occurring at 102 F. Pulse remained in neighborhood of 80 to 90 per minute, rising to 120 per minute just before death. On the penultimate day, the patient became dyspneic requiring nasal oxygen. Coarse moist rales appeared in both bases and a definite right hemiplegia of the upper motor neuron type with positive Babinski was noted. There was moderate nuchal spasm and a positive Brudzinski sign. A few ecchymotic areas appeared on the forearms. There was a right subconjunctival hemorrhage. The left forearm suddenly became cold, the nails cyanotic, and no pulse was felt below the elbow. The arm was wrapped in cotton and a hot water bottle was applied. Several petechial hemorrhages were noted in the conjunctivae. On the last day there was still no pulse in the forearm but it was now warm. The nails were still cyanotic. The right hemiplegia was maintained. The meningeal signs were less marked and the patient developed marked pulmonary edema and coma. Hypertonic glucose and aminophyllin were given intravenously but produced only temporary improvement after which the patient died.

Discussion

DR EMANUEL APPELBAUM. The diagnoses considered in this case were (1) coronary artery disease, with recent closure and mural thrombosis, (2) rat-bite fever with septicemia and vegetative endocarditis. We leaned toward the latter. In order to shed more light on the clinical interpretation of this case, it is necessary to discuss briefly the bacteriologic and clinical features of rat-bite fever. Unfortunately, both the bacteriology and the clinical status of this disease are at present in a state of confusion.

In regard to the bacteriology, the infecting agent recovered has usually been one of two organisms.

A. In the majority of instances a *Spirillum* known as *Spirillum minus* (*Spirochaeta morsus muris*) has been recovered. The organisms may be found on dark-field examina-

tion of infected tissue but is best demonstrated by inoculation of the patient's blood or tissue into animals. It is not obtained by blood culture. It is to be noted that *Spirillae* are normally found in mice.

B. In a smaller number of cases an entirely different organism, *Haverhillia multiformis* (*Streptobacillus moniliformis*) has been found. It is obtained by blood culture.

Which of the two organisms under consideration is the etiologic agent of rat-bite fever is a controversial subject.

Clinically, we have to consider these entities.

A. Oriental sodoku which is always caused by a rat bite and is sporadic in occurrence. The etiologic agent is *Spirillum minus*. The salient clinical features are (1) rat bite, (2) healing of the bite, (3) an incubation period of five to twenty-eight days, (4) recurrence of the primary lesion which becomes indurated, red, swollen, tender, and occasionally ulcerated but never shows pus, (5) a local lymphangitis lasting one to two weeks, (6) regional lymphadenitis, (7) development of chills and fever of a remitting or relapsing character, (8) the development during the first week of a purplish maculopapular rash with large, discrete lesions, (9) frequently there is a positive Wassermann.

B. *Haverhillia multiformis* septicemia due to rat bite. The etiologic agent of this case is the *Haverhillia multiformis* (*Streptobacillus moniliformis*), which is obtained by culture from the blood or joint fluid. The clinical features are similar to sodoku with the following exceptions: (1) primary lesion may not recur, (2) the cutaneous lesions are less striking and apt to be morbiliform or petechial, (3) the fever is less apt to be relapsing in type, (4) arthritis, very common.

C. Haverhill fever. This refers to an epidemic which occurred in Haverhill, Massachusetts, in 1926. The etiology was the *Haverhillia multiformis* which was recovered from the blood by culture. The clinical features were a sudden onset with chills and fever of a relapsing type, a morbiliform eruption and the presence of arthritis. It was probably a milk-borne attack.

Are sodoku and *Haverhillia multiformis* septicemia different disease entities? This is at present controversial.

In our case, the history of rat bite, the presence of cervical adenopathy, a report of a transitory petechial eruption, the lack of recurrence of the primary lesion, the presence of fever, but not of the relapsing type, favored the diagnosis of rat-bite fever with *Haver-*

hilia multiformis septicemia, although there was no evidence of arthritis. The presence of endocarditis was also postulated. This too, would favor the Haverhillia multiformis etiology, since there is one report in the literature of a case of vegetative endocarditis due to the Streptobacillus moniliformis and there is no record, to the best of my knowledge, of a Spirillum causing such a lesion.

DR HENRY C FLEMING I should like to mention Dr Blake's case from the Peter Bent Brigham Hospital which showed a vegetative endocarditis on necropsy and a streptothrix isolated from the vegetations on the mitral valve. In this case, Blake also isolated a streptothrix both in blood cultures during the life of the patient and at postmortem. If our case is one of rat-bite fever, then arsenicals might have been used.

DR APPELBAUM Dr Blake's case is the one I referred to in my discussion.

DR PHILIP GOLDSTEIN There was recently another case in a 2-year-old child who was bitten on the forehead by a rat. This child became ill, listless, ran a remittent type of fever, and finally died with a convulsion. At postmortem, as far as I know, there were no gross findings of any note.

DR MAX TRUBEK I think that one should strongly entertain the possibility of this case being one of ordinary bacterial endocarditis.

Present in the audience was a fourth-year medical student, from the College of Physicians and Surgeons, who had suffered from rat-bite fever, and he was called on to discuss his case *vide* article by Dr M H Dawson and G L Hobby (by invitation), Ph D *.

Presentation of Pathology

Primary	Acute bacterial endocarditis (possible Spirillum etiology)
	Cerebral embolism and infarction
Secondary	
Heart	Acute ulcerating bacterial vegetation—mitral valve Sclerosis of the aortic and mitral valves Coronary atherosclerosis Suppurative myocarditis—localized by extension
Lungs	Congestion and edema Emphysema
Spleen	Chronic perisplenitis
Kidneys	Multiple infarctions Nephrosclerosis

Bladder	Papilloma
Prostate	Hypertrophy Infarction
General	Anemia Conjunctival petechiae

DR DAVID M SPAIN The postmortem examination showed a fairly large, bulky, friable vegetation arising from the auricular surface of the posterior mitral valve leaflet. The vegetation invaded the mitral ring and extended into the myocardium to the epicardial surface of the heart. There was an infarction of the left side of the brain which involved the putamen, external capsule, and claustrum. Infarcts were also present in the kidneys and prostate. The clinical finding of hematuria was explained on the basis of a bladder papilloma. The original rat bite was well healed. In a typical case of rat-bite fever, this is usually not so. There have been very few autopsied cases of rat-bite fever. The histologic findings in these cases have revealed no specific lesions. The unhealed bite usually reveals a nonsuppurative granuloma. Skin lesions show dilated blood vessels and lymphocytic infiltration, while the viscera merely show changes reported in any febrile illness. In this case, macroscopic examination showed the histologic picture of infarction and the vegetation consisted of thrombotic material with many polymorphonuclear leukocytes, lymphocytes, early calcification, and minimal fibroblastic proliferation.

The bacteriologic workup was as follows (performed by two independent bacteriologists). Direct smears of the crushed vegetation stained with Giemsa and Gram stains revealed a Spirillum-like organism resembling the Spirillum minus. No other organisms were found. A Levaditi stain of the fixed tissue vegetation revealed a similar organism.

A significant fact is that no bacteria were cultured from the antemortem and postmortem blood and that no bacteria were found either on direct smear or culture of a vegetation of this type. This is a most unusual finding in this laboratory. This fact coupled with the above evidence leads one to make the assumption that the rat bite and, more specifically, a Spirillum was the possible etiologic agent of this endocarditis. It should be mentioned that Bayne-Jones claims the Spirillum has never been cultured directly from the blood. It also would have been wiser to inject the antemortem blood into a white mouse rather than into guinea pigs. Further study is being continued on laboratory animals with the hope of confirming our findings.

* Rat-Bite Fever (From the Edward Daniels Faulkner Arthritis Clinic.) Transactions of Association of American Physicians, 1939

Maternal Welfare

Committee's Program Adopted by Council

A RECENT study by the Maternal Welfare Committee, a subcommittee of the Council Committee on Public Health and Education of the Medical Society of the State of New York, revealed the apparent need for a comprehensive statewide maternal welfare program. The survey showed a comparatively high maternal mortality rate in certain communities. There was also evidence that drastic reduction in maternal mortality rates had been accomplished in other communities, apparently resulting from efforts of county society programs. The conclusion drawn was that certain counties might well establish programs aimed at reducing maternal mortalities and that others should continue their efforts so as to maintain progress already accomplished.

The committee recommended to the council that it be permitted to set up an Advisory Committee on Maternal Welfare to consist of twelve regional chairmen, each representing certain geographical areas of the state (This committee is listed below.) It further recommended that full cooperation with the State Department of Health be obtained. Also it was suggested that the section on Maternal Welfare be continued in the NEW YORK STATE JOURNAL OF MEDICINE. These recommendations were approved by the council.

It is planned in the very near future to set up a similar Advisory Committee to deal with pediatric aspects of the problem.

The functions of the regional chairmen as outlined by the Maternal Welfare Committee are as follows:

- 1 To establish contact with the various county society maternal welfare committees and to assist in county programs in any possible manner
- 2 Survey maternity facilities in district and report with recommendations and suggestions
- 3 Become familiar with district statistics on maternal and child welfare.
- 4 Plan district postgraduate refresher courses
- 5 Distribute literature when available
- 6 Stimulate formation of blood banks, plasma banks, or lists of available blood donors
- 7 Awaken public interest by means of available publicity methods
- 8 Organize obstetric conferences

The Maternal Welfare Committee recommends the obstetric conference as the best available method of practical postgraduate education. It is the aim to establish such conferences in each county, groups of counties, or districts.

The conferences consist principally in the presentation of actual maternal mortalities. Such mortalities are presented in the form of carefully prepared, concise, case reports. Patient, physician in attendance, and locality of the mortality are kept anonymous. Cases may be exchanged with another county, reviewed only after considerable time has elapsed, or, on re-

quest, will be provided by the Committee on Maternal Welfare from elsewhere in the state.

The only purpose of the obstetric conference is self-education. Hence, preventability should not be assigned and no statistics on preventability kept. Every physician in the community is invited to attend.

Experience has shown that the anonymous type of presentation lends to an open discussion of cases. The method is available in every community and is an excellent mechanism for the postgraduate education that every physician desires but often finds hard to obtain.

Each regional chairman is familiar with the *modus operandi* of the obstetric conferences and will be available to assist any local group in establishing such conferences. The natural medium for such presentations would seem to be the county medical society.

New York State is in need of a definite maternal welfare program. Such a program should obviously be under the supervision of the Medical Society of the State of New York. However, the actual programs must be conducted by the county medical societies. The regional chairmen should serve the purpose of correlating the activities of the local groups with that of the State Society. The Maternity, Infancy, and Child Hygiene Division of the New York State Department of Health is cooperating and affording valuable assistance in the program.

It is the earnest desire of the Maternal Welfare Committee that all physicians in New York State who include any maternity work in their practices, as well as others interested in maternal welfare, will familiarize themselves with the objectives of this program. Any advice or recommendations will be greatly appreciated and given due consideration. Each community, of necessity, must be interested in its local child and maternal mortality rates. It is hoped that each county society will establish a definite maternal welfare program.

"MORE OR LESS OF A QUACK"

"A wholesome effect on the shady fringe" is expected by *Minnesota Medicine* to result from the strong rebuke administered by Judge Loevinger of the district court to a chiropractor convicted of the illegal practice of medicine in St Paul. The man was a railway postal clerk who did business as a healer in his spare time. A young divorcee, of 19 summers, went to him for "delayed menstruation," which he tried to remedy with an electrical device. She became ill, was taken to a hospital, and demanded \$300 from the postal-clerk-chiropractor, who appealed to the police for protection. Instead, he was arrested, convicted, and fined \$200, which he promptly paid. Said the judge:

"You have been licensed by the state to practice a particular form of healing. You have not been licensed to practice any other form of healing. When you undertake to perform any other form of healing beyond that which you have been licensed, you are perpetrating a fraud upon your patients as well as violating the law. It is unfortunate that when some people are in physical trouble, when they are ill or have any other physical difficulty, that instead of going to a person who is qualified to treat them they are likely to go to some person who is more or less of a quack in that particular line. I am not reflecting on your ability as a chiropractor, but on any other line you are just a quack. You have no authority to practice medicine and anyone who pays you any money therefor pays it to you under false pretense. It is the purpose of the law to discourage that sort of thing so that people with pain and suffering shall not be preyed upon by people who are not qualified to render competent services."

"Should you attempt to practice any other form of medicine than chiropractic and appear in court again I suspect the court will be considerably less considerate than I think it has been this time."

TO SEND BLOOD PLASMA TO BRITAIN

How new techniques for collecting and transfusing blood, utilizing plasma rather than whole blood, have made it possible for thousands of Americans to donate their blood for the British cause in the European war is told by Edith Roberts, Kokomo, Indiana, in *Hygeia, The Health Magazine*.

By the use of plasma, the liquid portion of the blood after the red and white cells are removed, a healthy donor may aid a wounded sufferer thousands of miles away. "The difficulty of direct blood transfusion at the scene of any great disaster which shatters human bodies is evident," the author says. "It is almost equally impossible to effect the necessary transfusion with blood which has been donated and preserved, for the simple reason that, after a very few days outside the body, whole blood deteriorates, its cells break down, and it cannot be transported and used."

"This is where plasma enters the picture. For plasma does not have to be 'grouped' or 'typed' as whole blood must be before transfusion, else the result may be fatal. Plasma from one human being can be given to any other, plasma can be transported long distances and preserved for a year or more. It can even be dried and redissolved."

"Under the fearful stress of the present conflict, there is being developed and perfected an astounding technic for collecting and distributing human plasma in quantity."

"At present blood plasma is being accepted from donors only in New York City. But as the technic of its collection in quantity is perfected, the movement will be extended from coast to coast."

"Some plasma is being prepared in England, but the bulk of it must come from us. For in Britain's crowded hospitals there is too little time or space to devote to the careful, tedious process."

There are said to be more than five thousand quack "cancer-cures" on record.

Every calling is great, when greatly pursued.
—Mr Justice Holmes

Medical Preparedness

Examinations for Appointments in the Medical Corps of the U S Navy

THE Surgeon General of the Navy, Rear Admiral Ross T McIntire (M C), U S N, announces the next examination for appointments as commissioned officers in the Medical Department of the Navy will be held at all of the larger naval hospitals and at the Naval Medical Center, Washington, D C, on May 12 to 15, inclusive, 1941. Applicants for appointment as Assistant Surgeon, effective approximately two months from date of examinations, may now request authorization to appear for examination. Requests for such authorization should reach the Bureau of Medicine and Surgery prior to April 21, 1941.

Applicants for appointment as Assistant Surgeon are required to be citizens of the United States between the ages of 21 and 32, graduates of Class "A" medical schools, to have had at least one year of intern training in a hospital accredited for intern training by the Council on Medical Education and Hospitals of the American Medical Association, and to meet the physical and other requirements for appointment.

The Medical Corps of the Navy is being increased in strength proportionate to the expanding Navy and United States Marine Corps. Service for medical officers is active professionally and attractive in assignments at sea, on shore duty, and on foreign shore stations. In the normal rotation of assignments every practicable consideration is given the officer's preference for the type of duty he desires. The Naval Medical School at the Naval Medical Center, Washington, D C, offers a course of postgraduate instruction in those branches of medicine which apply particularly to naval service. Under normal conditions newly appointed officers are assigned to this course upon their

entry into the service or during their first few years of naval service.

Naval medical officers are encouraged to develop a specialty after they have completed their first cruise at sea. Shortly before completion of his sea duty, the Navy doctor may request special training in the Medical Department specialty in which he is interested. Such requests are acted upon by a special board in the Bureau of Medicine and Surgery, and, if approved, the Navy doctor is sent to a hospital for training and experience in that specialty for one year. Upon completion of this training, he is assigned to postgraduate instruction at one of the many medical centers in the United States for a period up to one year after which, insofar as is practicable, he is retained in that type of duty. Some of the specialties in which qualifications may be obtained are surgery, medicine, otolaryngology, x-ray, laboratory, pathology, public health, psychiatry, deep-sea diving, aviation medicine (flight surgery), gas warfare, and tropical medicine. Several officers have been trained in research particularly applying to problems arising in submarine and aviation activities.

The naval service affords excellent opportunities for professional advancement. Medical officers receive the same pay and allowance as other officers of the Navy in corresponding ranks and the equivalent amount of service.

A circular of information for applicants for appointment as medical officers of the Navy, containing full information regarding physical requirements, professional examinations, rates of pay, and promotion and retirement data may be obtained by addressing the Bureau of Medicine and Surgery, Navy Department, Washington, D C.

BRITAIN TO LICENSE UNITED STATES PHYSICIANS

Canadian and United States physicians are being licensed by Great Britain for the duration of the war, the regular London, England, correspondent of the *Journal of the American Medical Association* reports.

"The government has made an order under the Emergency Powers Act, passed for the purposes of the war, enabling the General Medical Council to register for the period of the emergency Canadian and United States physicians. They will thus be able to join the Emergency Medical Service with the same privileges as British physicians. Previously we have never had medical reciprocity with the United States."

TRANSPLANTED HUMAN BUDS IN THIS WAR

The effect on their health of the transplantation of 750,000 children removed from London to escape Nazi bombs is studied in a new book called *Borrowed Children* by Mrs St Loe Strachey. While some of them suffered from fears, anxieties, and homesickness, to many of them, says a reviewer, "this transplantation to a new and often better environment resulted in great benefits. Better and more ample food provided at regular meals, regular hours for rising, and more healthful hours for retiring were among these. Country experiences, where for the first time these children had intimate contact with plants and animals, had great value."

STOMATOLOGIC NOTE FROM PUERTO RICO

Mayaguez, Puerto Rico. Robert Gumbs was appointed vice-consul on February 12, 1880, and Alfred A. Saliva was appointed consular agent on February 1, 1892.

Medical News

Nonprofit Medical Expense Insurance

THE Medical Society of the County of Westchester at its meeting on January 21, 1941, took definite action to express its opinion of the merits of the six corporations established under Section IX-C of the Insurance Law for operation in New York City and surrounding counties. A committee analyzed these corporations and made the following report, which was adopted unanimously.

For several years the medical profession in New York State, and particularly the Medical Society of the County of Westchester, has favored the principle of medical expense insurance to enable the public voluntarily to budget against the costs of expensive or prolonged illnesses.

Both the County and State societies favored the adoption of legislation to permit this development.

The Committee on Medical Economics has examined, on behalf of the Society, the plans of six organizations established under Section IX-C of the Insurance Law, as follows:

- A—Medical Expense Fund of New York Inc
- B—Group Health Cooperative, Inc
- C—American Plan for Medical and Surgical Care, Inc
- D—Medical Guild Foundation, Inc
- E—Association for Prepaid Medical Care, Inc
- F—Associated Health Foundation, Inc

Three of these plans provide for payment of the physicians' fees on a fee for service basis, the remaining three plans providing for payment of a single annual capitation fee per subscriber.

The mechanism by which the medical care is to be provided is essentially the same for all of these plans, insofar as the patient is concerned.

Plans identified above as C, D, E, and F, are all characterized by the following objectionable features:

- 1 There are in general no income limits or extremely high income limits for eligibility of the subscriber.

- 2 An unlimited amount of service may be required of the physician in any contract year.

- 3 A lengthy period of notice is required of the physician to terminate his contract.

- 4 There is no stated minimum compensation guaranteed to the physician, even for service to patients in the highest income brackets.

- 5 The physician is permitted to make no private charges to supplement the unspecified remuneration to be received from the corporation.

- 6 Three of these plans require no deductible charges to be paid by the subscriber as a safeguard against unwarranted demands for service, and in the fourth plan the deductible charges are not required of group enrollees.

Your Committee recommends that the plans of the American Plan for Medical and Surgical Care, Inc., the Medical Guild Foundation, Inc., the Association for Prepaid Medical Care, Inc., and the Associated Health Foundation, Inc., be disapproved by the Society.

There remains one organization offering medical expense insurance on a fee for service basis, namely, the Medical Expense Fund, Inc., and one organization, the Group Health Cooperative, Inc., offering unlimited medical care on a per capita, yearly fee basis.

The Group Health Cooperative proposes to offer the patient an unlimited amount of general care, including an annual health examination and such preventive services as the individual may elect to obtain, for an annual per capita fee of \$6.60 for each adult enrolled. Added capitation fees are provided for children. Specialists are to be paid on a fee for service basis, calculated according to units of service rendered. The actual remuneration for specialists is estimated to approximate two-thirds of the Workmen's Compensation Schedule of Fees. The general physician may make an additional charge to the patient in the amount of \$1.00 for the first call in any home illness. The income limits for eligibility under the Group Health Cooperative plan are \$2,000 for an individual, \$3,000 for a couple and \$300 additional for each additional dependent.

Although Group Health Cooperative emphasizes to the lay public the advantages of unlimited preventive care and a periodic health examination included in its plan, nevertheless, the remuneration provided the physician is evidently calculated on estimated needs for curative medical service, no financial provision being made to pay for preventive services. A thorough physical examination alone should be worth more than the annual capitation fee. To add to this the possible demand for accepted preventive services, such as the use of cold vaccine, poison ivy, and other antigens preventively, etc., would render the capitation fee even more inadequate when contrasted with a fee for service plan.

Without questioning the value of these elective procedures in themselves, the Committee does not approve of the inclusion of such procedures in an insurance program until proved to be actuarially sound. Certainly such procedures should not be included unless provision is made for adequate remuneration for them.

The Committee's study leads it to question the adequacy of the capitation fee as applied to Westchester County, in the face of possible contingent demands for medical services. It is axiomatic that inadequate financial returns in the long run inevitably produce inferior service. The Committee finds further that the provisions for the control of abuse by subscribers are indefinite, and, in the opinion of the Committee, totally inadequate.

The Committee is opposed to the principle of capitation fees. We find no social need or justifi-

fication for this basis of remuneration. We find no assurance that it will attract the willing participation of any considerable number of physicians, and there is every indication that it will lower the standards of remuneration as against those now obtaining in the income group which can be expected to purchase this insurance.

Our objections to the plan of Group Health Cooperative are recognized to be largely theoretic. Apart from its underlying philosophy and its principal features, with which we do not agree, it may be said that this plan has been carefully thought out.

The Committee recommends that approval of the plan of Group Health Cooperative be withheld.

The Committee has made a very careful examination of the plan of Medical Expense Fund, Inc. The main assumption of this plan is that the primary need for the application of the insurance principle is to protect the individual against the cost of serious or prolonged illness. We are in agreement with this philosophy. The Medical Expense Fund, Inc., has met the principles set forth by the Medical

Society of the State of New York to govern medical expense insurance. It is so organized that the medical societies of the Metropolitan area effectively control its policies through their duly elected delegates who are the voting members of the corporation. The assumptions upon which the Medical Expense Fund expects to operate are also theoretic in part, but they seem to us to be the soundest, most reasonable, and fairest, both to the patient and to the physician, of all the plans examined.

There are, of course, questionable, even objectionable features to this plan, but they largely relate to details which may be corrected if and when experience indicates changes in the plan are needed. There is, of course, no proof or even any convincing precedent that this plan will succeed, but of all the plans considered it is the one that most closely follows the established pattern of medical practice and accepted principles of insurance. It is also as clearly and completely thought out as any other plan.

We recommend that the Society approve the purposes and plan of organization of the Medical Expense Fund, Inc.

County News

Bronx County

On December 7, 1940, the Bronx Medical Association tendered its charter member, Dr Nathan B Van Etten, president of the American Medical Association, a testimonial dinner at the Bronx Schnorer Club to celebrate his fiftieth year in the practice of his profession. There was an attendance of over 150. The Association availed itself of the opportunity to present Dr Van Etten with a watch on which was inscribed "To Dr Nathan B Van Etten, President of the American Medical Association, 1940, for fifty years zealous exponent of medical ideals and ethics, with high regard from the Bronx Medical Association"—Reported by Carl Wurm, Jr., M D, Secretary.

Broome County

Dr Arthur S Chittenden, of Philadelphia, one of Binghamton's leading physicians and surgeons until his retirement in 1934, spoke at a meeting of Binghamton Academy of Medicine on January 21 in City Hospital Auditorium.

His topic was "Our Town and Its Doctors—Past, Present, and Future."

Dr Lester H Quackenbush, of Binghamton, who died on January 14, at the age of 79, was a past-president of the county society and of the Binghamton Academy of Medicine. He had practiced medicine for fifty years.

Clinton County

The new officers of the county society are as follows: president, Dr Eric D Pearson, Plattsburg, vice-president, Dr Dana A. Weeks, Peru, secretary, Dr James J Reardon, Plattsburg, treasurer, Dr Kenneth M Clough, Plattsburg, censors Drs Sidney Mitchell, Elmer Wessell, and Ira A Rowison, all of Plattsburg.

Columbia County

At the annual meeting of the county society these officers were chosen for 1941: president,

Dr Rosslyn P Harris, Hudson, vice-president, Dr Ralph F Spencer, Hudson, secretary-treasurer, Dr Henry C Galster, Hudson, censors Dr Clark G Rossman, Hudson, Dr Sherwood V Whitbeck, Hudson, Dr Frank C Maxon, Chatham, Dr Rosewell D Shaw, Stottville, and Dr Leonard D Carpenter, German-town.

Erie County

Federal agencies were blamed for "misunderstandings between the public and the medical profession" by Dr Nelson W Strohm on January 20 in Hotel Statler in his inaugural address as president of the county society. To help correct this, doctors must become more interested in politics, he asserted.

"Nationally," he said, "the profession was at one time called a monopoly and court action instituted against it, but when the same federal agencies want something of it for nothing—such as the preparedness program, Selective Service boards, advisory boards, etc—they refer to it as a profession, so that it is no wonder that the laity wonders just what it is."

"It is well known," he warned, "that you cannot give the state power to do something for you without giving it the power to do something to you."

"The family physician or general practitioner must be revitalized and urged into active leadership of all political movements concerned with the physical, moral, and mental welfare of every citizen."

Commenting on the society's proposed medical welfare plan for Erie County, in which the indigent patient would be given the privilege of choosing his own hospital and physician, Dr Strohm cautioned the members to be wary of plans "proposed by lay groups."

"The one thing we must continue to insist on," he said, "in this or any other plan is that the patient's health and welfare come first and that he must remain the employer of his physician."

A course of lectures in vitaminology, continuing fifteen weeks on Wednesday evenings, is being given at Meyer Memorial Hospital in Buffalo by Dr. Julia E. Lockwood, instructor in physiology at the medical school of the University of Buffalo.

Dr. John G. Meidenbauer, of Buffalo, who died on January 24 at the age of 82, had practiced medicine for over fifty years.

Fulton County

Members of the county society voted to sponsor a course of lectures on traumatic surgery at the meeting held at the Hotel Johnstown on January 16.

All physicians in the county, whether members or not, are invited to attend these lectures which will be held periodically throughout the year.

The group heard Dr. George Lenz tell of his experiences in forty years of surgery in Fulton County.

Following the meeting, which was presided over by Dr. B. A. Winne, a turkey dinner was served. There were 30 members present.

Greene County

The regular quarterly meeting of the county society was held on January 14 at Memorial Hospital, Catskill. Dr. Herbert Weinauer, the new president, presided and the speaker was Dr. Harry V. Judge, of Albany.

Herkimer County

Members of an official advisory health preparedness committee for Herkimer County, to cooperate with the county defense council and state health commission, are announced by Assemblyman Mailler, health commission chairman.

They are county executive or representative, Dr. L. P. Jones, Lion, district state health officer in charge of area, Dr. Samuel Hyman, Utica, county health officer, Dr. L. L. Kelley, Middleville, chairman of medical preparedness committee of county medical society, Dr. Fred C. Sablin, Little Falls.

County public welfare commissioner William Dize, Middleville, representative of county hospital, George J. Sluyter, Herkimer, representative of state dental society, Dr. Howard James, Mohawk, representative of Red Cross, Dr. Duane B. Madison, Herkimer, representative of state nurses association, Miss Jane Boote, Herkimer, representative of state pharmaceutical society, Edward Sodolski, Herkimer, Dr. A. B. Santry, Little Falls health officer, and William Van Allen, Little Falls welfare commissioner.

Kings County

The scientific program of the meeting of the county society on January 21 featured these topics and speakers: (a) Inaugural Address "The Doctor Looks Ahead," Dr. Maurice J. Dattelbaum, (b) Address "The Civilian Surgeon in War," Brigadier General Raymond F. Metcalfe, commanding general, Army Medical Center, Washington, D. C., (c) Address "Medical Service in Our Navy During Times of Expansion," Commander Guy B. MacArthur, M. C., U. S. Naval Hospital, Brooklyn, N. Y.

The Brooklyn Urological Society held a

meeting on February 11. The scientific program was as follows: "A Case of Lymphosarcoma of the Kidney Simulating Carbuncle," by Dr. Bernard Davidson, "Experiences with the Treatment of Incontinence in Women," by Dr. Ray McCune Bowles (by invitation), "Experiences with the Treatment of Carcinoma of the Bladder," by Dr. Ray McCune Bowles (by invitation). The discussion was opened by Drs. Nathaniel P. Rathbun, Charles S. Cochrane, and Paul W. Aschner.

The Ocean Medical Society met on January 20 at Aperiion Manor and heard an address on "Cancer of the Colon," by Dr. John E. Jennings.

The Williamsburg Medical Society listened to a paper on "Vitamins: Uses and Abuses," by Dr. Heinemann, of Yale University, at the meeting on February 10 at the Leon Louis Auditorium.

The annual meeting and election of officers of the Pan American Medical Association, Brooklyn and Long Island Chapter, was held at the Montauk Club on December 6, 1940. The following officers were elected: president, Dr. Edwin A. Griffin, vice-presidents, Drs. Thomas B. Wood, F. Raymond Surber, Siegfried Block, secretary, Dr. Frank E. Mallon, and treasurer, Dr. Morris W. Henry.

The next scientific meeting will be held on February 25 at 9:00 P. M. in the Nurses' Lecture Hall of the St. John's Hospital of Brooklyn, 480 Herkimer Street, near Albany Avenue. An interesting program has been arranged: (1) "Sudden Death," Dr. Theodore J. Curphey, pathologist, Meadowbrook Hospital, and coroner in Nassau County, (2) "Arterial Hypertension," Dr. Henry A. Schroeder of the Rockefeller Institute, (3) "The Management of Embolism and Thrombosis, the Use of Heparin," Dr. Merrill N. Foote. The medical profession is cordially invited.

Dr. Edward L. Bauer of Jefferson Medical College, Philadelphia, was the principal speaker at the annual installation of officers of the South Brooklyn Medical Society in the Baltic Street Health Center, on January 9. Dr. Bauer discussed "Prevention and Treatment of Vitamin Deficiency Diseases in Children."

The Homeopathic Medical Society of Kings County held a scientific session in the lecture room of Prospect Heights Hospital, Washington Avenue and St. John's Place, on January 9.

Dr. Thomas B. Wood of Coney Island Hospital spoke on "The Acute Ear," and the discussion was led by Dr. A. Roth. Dr. Howard T. Blair is president of the society.

Livingston County

Dr. P. M. Ostrander has announced his retirement from the practice of medicine after serving the people of Nunda and Portage townships for fifty-seven years.

Madison County

The winter meeting of the county society was held at the Hotel Oneida, Oneida, on January 23. The program was as follows: (1) "Active and Passive Immunizations in Children," by Dr. Brewster C. Doust, Syracuse. Discussion was opened by Dr. Ernest Freshman, Oneida.

(2) "Cavernous Sinus Thrombosis and Heparin Treatment," by Dr. Irl H. Blaisdell, Syracuse. Discussion was opened by Dr. Gordon D. Hoople, Syracuse. This talk was illustrated by lantern slides. (3) "Low Back Pain from Protruding Intervertebral Disks," by Dr. Arthur D. Ecker, Syracuse. Discussion was opened by Dr. Howard Beach, Oneida. Motion pictures were shown.

A course of lectures on traumatic surgery, arranged by the Madison County Medical Society by Dr. Henry H. Ritter, New York City, was given at the Hotel Oneida, Oneida, New York, on Wednesdays at 8:30 p.m. On January 29, Dr. Willis W. Lasher lectured on "Bursitis, Sprains, and Strains", on February 5, Dr. H. M. Bergamini was heard on "Abdominal Injuries", and on February 12, Dr. David Goldblatt, on "The Treatment of Burns and Hand Infections". All three doctors are from New York City.

In addition to the above course, the following miscellaneous lectures will be presented in co-operation with the State Department of Health on February 19, "Ments of Surgery, X-ray, and Radium as Applied to Cancer," by Dr. Louis C. Kress, director, Division of Cancer Control, State Health Department, on February 26, "Postabortal and Postpuerperal Infections," by Dr. Ferdinand J. Schoeneck, of Syracuse, on March 5, "Cancer of the Gastrointestinal Tract," by Dr. J. P. O'Brien, of Buffalo, and on March 12, "Rheumatic Fever," by Dr. Homer F. Swift, Hospital of the Rockefeller Institute for Medical Research, New York City.

Monroe County

Draft registrants rejected for remediable defects will be enabled to correct their physical disability through efforts announced by the County Tuberculosis and Health Association.

Men rejected for teeth defects will be referred to the Rochester Dental Society. Seventeen eye physicians have agreed to examine the eyes of men turned down for visual defects, particularly those with conditions that can be corrected with glasses, according to Dr. Lyman C. Boynton, medical consultant of the Tuberculosis and Health Association. The association will sponsor a project to raise funds to buy glasses, he said.

Corrective services of the association have previously functioned effectively to aid trainees in shop schools for war industries, Dr. Boynton pointed out, and these services will be made available to men rejected by draft examiners.

At a county society meeting he reported that out of 1,700 Monroe County men examined for the draft more than 400 had been rejected. Of the 400, 90 had correctable defects, 80 per cent of the 90 were turned down because of their teeth, 15 per cent for eye trouble, and 5 per cent for other reasons.

Through its Medical Defense Committee, the county society will aid in removing the draft "bottle-neck" of physical examinations by assigning 110 additional physicians to help in mass examinations for nine of the county's nineteen draft boards.

Results of a year's study of pneumonia as observed in seven Rochester hospitals were discussed on January 21 at a special pneumonia institute.

Taking part in the institute in the Academy of Medicine were leading state figures in the fight on pneumonia, as well as physicians of Monroe, Livingston, Wayne, and Ontario counties.

The study, covering the period from November, 1939, to November, 1940, and including an analysis of 758 cases of clinical pneumonia, is one of the most intensive ever undertaken in the nation, according to Dr. David B. Jewett, chairman of the pneumonia control committee of the county society.

The study was discussed by Dr. Maxwell Finland, assistant professor of medicine at Harvard, assistant physician of Thorndike Memorial Laboratory in Boston City Hospital, and member of the technical advisory committee on pneumonia control for New York State, and by Dr. Edward J. Rogers, of Albany, director of the State Bureau of Pneumonia Control.

The general discussion was led by Dr. O. W. H. Mitchell, of Syracuse, chairman of the State Society's committee on public health and medical education. Dr. C. Stewart Nash, president of the county society, presided.

The institute was under auspices of the State Society, county society, and the State Bureau of Pneumonia Control.

Nassau County

According to a recent Lions Club talk by Dr. J. Louis Neff, secretary of the county society, the health of Nassau County is superior to any other county in the nation. Regarding the health of draftees, the speaker asserted that there were fewer medical rejections in Nassau County than in any other county in the country.

New York County

The program of the county society at the meeting on January 27 was as follows: (1) address of the retiring president, (2) address of the incoming president, (3) "Conditions Frequently Mistaken for Hyperthyroidism. Analysis of 1,500 Cases Diagnosed as Thyroid Disorders," by Dr. Alfred H. Noehren, Buffalo, by invitation.

The annual meeting of the New York Heart Association, followed by a scientific session, was held at The New York Academy of Medicine on January 23.

Dr. Ernst P. Boas, chairman of the Association, gave a report on the year's activities. Other speakers were Dr. John G. Gibson, II, of Peter Bent Brigham Hospital, Boston, and Dr. C. Sidney Burwell, of Harvard University Medical School. Dr. Gibson spoke on "Some Observations on the Blood Volume in Heart Disease," and Dr. Burwell's topic was "Studies of the Circulation During Pregnancy." Drs. Charles Warren and Harold J. Stewart led the discussion.

Dr. Colin Luke Begg, specialist in genitourinary diseases who had practiced in New York since 1901 and was one of the founders of the American Urological Association, died on January 15 of a heart attack in a taxicab shortly after leaving The New York Academy of Medicine. His age was 67.

Dr. Francis Carter Wood will speak at The

New York Academy of Medicine on February 27 on "What We Do Know about Cancer," in the series of "Lectures to the Laity"

Oneida County

Dr J B Lawler was elected president of the county society to succeed Dr F John Rossi at the annual meeting on January 14 Dr Rossi spoke on "The Irregularities of the Practice of Medicine" Other officers named were vice-president, Dr Robert Sloan, secretary, Dr James I Farrell, treasurer, Dr H D MacFarland, librarian, Dr T Wood Clarke, board of censors Dr William Hale, chairman, Dr B F Golley, Rome, and Drs Rossi, A F Gaffney, and F M Miller, Sr

Dr Dan Mellen, Rome, and Dr J F Kelley were elected to the House of Delegates of the State Society With Dr Sloan, who was elected last year for two years, and Dr Hale, vice-speaker of the House, the society now has four votes in that body

Dr Philip L Turner was elected president of the Utica Academy of Medicine at the annual meeting on January 16

Other officers chosen were vice-president, Dr Fred G Jones, secretary, Dr A. R. Hatfield, Jr, treasurer, Dr H D Parkhurst, trustees, Dr William W Wright, retiring president, Dr Harry D Vickers, and Dr Robert C Hall

Dr William Crawford White, clinical professor of surgery of Columbia University and surgeon at Roosevelt Hospital, New York City, discussed "The Surgical Diseases of the Large Bowel" He stressed the use of radium

Onondaga County

No information on results of physical examination of men under the Selective Service System may be given out by local boards, it is noted in a letter concerning the county society's proposed study of cases of rejection

The society sought the names and addresses and causes of rejection of registrants with a view to determining the extent of a social welfare program needed to remedy the causes of rejection

Eye and teeth deficiencies have caused the bulk of physical disqualification at the induction station, but no information has been available as to the chief grounds for disqualification of men by local board medical examiners

Ontario County

The Canandaigua Medical Society, at its annual meeting held with Dr A. W. Armstrong, West Lake Road, elected these officers president, Dr Hubbard K Meyers, vice-president, Dr James F Maltman, and secretary and treasurer, Dr C J Bobeck Dr F C McClellan and Dr John H Pratt were elected directors for two years, and Dr M R Blakeslee, of Shortsville, and Dr L A Stetson, were elected directors for three years, with Dr McClellan as chairman

Orange County

Members of the Newburgh Bay Medical Society elected Dr A. W. Beck, of Monroe, as president on January 14 to fill a vacancy caused by death of Dr Leo C DuBois, of Newburgh, on January 8 The annual meeting of the society was held in the Palatine Hotel

After the election, Lawrence Gould, radio commentator, spoke on "Keeping the War Out of America."

Other officers named included Dr Earl R VanAmburg, vice-president, Dr Theodore Proper, of Newburgh, treasurer, Dr C W Layne, of Newburgh, secretary, Dr Charles E Townsend, of Newburgh, auditor, and Dr H L Stephens, of Walden, Dr C G Lee, of Highland Falls, Dr P E Banks, of Newburgh, and Dr Paul Traub, of Washingtonville, trustees

Queens County

The county society at its meeting on January 28 listened to an address on "The Present Status of Radiation Therapy in the Treatment of Malignant Disease" by Dr William J Hoffman, assistant surgeon, Skin and Cancer Unit, Post Graduate Hospital, associate surgeon, Queens General Hospital, consultant, Neoplastic Diseases, St John's Hospital. The discussors were Drs Alfred Angrist, Morris S Bender, Edward A Flemming, Leonard Goldman, Irving Pontemon, Francis G Riley, and Joseph S Thomas.

The Friday Afternoon Talks are as follows February 7 at 4 30 P M—"Chronic Heart Disease—Diagnosis and Treatment," by Dr Clarence de la Chapelle, chief, Cardiac Clinic, Lenox Hill Hospital, physician, Bellevue February 21, at 4 30 P M—"Recent Advances in Diagnostic Radiology," by Dr Bernard S Epstein, assistant radiologist, Jewish Hospital.

The Rockaway Medical Society held its eighteenth annual beefsteak on January 30 in the Daniel M O'Connell Post, No 272, American Legion Clubhouse, 92nd Street, Rockaway Beach. Dr Louis A Sarrow was general chairman.

A professional entertainment was given and Dr Joseph Baum served as toastmaster

Rensselaer County

Captain George A Ketler, Medical Corps, United States Army, examining physician at the Albany induction center, was a speaker at the meeting of the county society at the Troy Health Center on January 14.

Captain Ketler clarified several items of the examination of draftees and outlined the fundamental factors in regard to the physical standards required for military service

During the business meeting, the society voted to conduct its meetings at The Hendrick Hudson in the future The society felt that better facilities and atmosphere for the meetings were available at the hotel and that larger attendance would result

Dr Charles W Hamm, retiring president, submitted his annual report and gave an interesting résumé of the history of the county society from its inception to date Reports on the activities of the last year were also received from the heads of the various committees

Dr John Sibbald, new president of the society, presided for the first time

Suffolk County

The new officers of the county society are president, Dr George Bergmann, Mattituck, first vice-president, Dr David Corcoran, Central Islip, second vice-president, Dr Archie M

Baker, Lindenhurst, secretary, Dr Edwin P Kolb, Holtsville, assistant secretary, Dr Willetts W Gardner, Patchogue, treasurer, Dr Grover A Sillman, Sayville, censors Drs Paul F Nugent, Leon J Barber, Louis F Garben, George Thompson, and Cyril E Drysdale

Warren County

Following are the officers of the county society for 1941: president, Dr Edward J Fitzgerald, Glens Falls, vice-president, Dr James A. Glenn, North Creek, secretary-treasurer, Dr Roger S Mitchell, Glens Falls, censors Dr Hilton H Dier, Lake George, Dr James B Shields, Glens Falls, and Dr Herbert A Bartholomew

Washington County

Dr L Whittington Gorham, professor and director of the department of medicine, Albany Medical College, and physician-in-chief, Albany Hospital, addressed the county society on January 16 at its meeting in the Mary McClellan Hospital, Cambridge

Wayne County

The first in a series of six lectures on medical topics to be held every two weeks was given on Tuesday, February 4, at a dinner-meeting at the Hotel Wayne in Newark.

The lectures are sponsored alternately by the Wayne County Medical Society and the Newark

Doctors' Club. Dr Frederick Wetherell, Syracuse, read a paper on "Gorier and Its Management" at the first meeting followed by a discussion by Dr C W Webb and staff

Westchester County

Dr Harry Klapper was elected president of the White Plains Medical Society at a meeting held at the Gedney County Club on January 14

Dr Klapper succeeds Dr G V H Hunter. The vice-presidency went to Dr J R. Montgomery, incumbent, and Dr Harold Nottley was named secretary to replace Dr Klapper. Named to the board of governors for two years were Dr Hunter and Dr James F D'Wolf, both succeeding Dr D C McElligott and Dr R B Hammond.

Following the meeting and election Dr D E Copple, of Pleasantville, presented a travelogue picture of England and Wales, in color, as they appeared before the war

Wyoming County

The officers of the county society for 1941 are as follows: president, Dr Clifford H Harville, Warsaw, vice-president, Dr Paul A. Burgeson, Warsaw, secretary-treasurer, Dr Oliver T Ghent, Warsaw, delegate to state convention, Dr Henry S Martin, Warsaw, censors Drs L Hayden Humphrey, Silver Springs, Mary T Greene, Castile, and George A. McQuilkin, Varysburg

CORRECT DIAGNOSIS

A man enters the doctor's office. "Doc, I want a thorough examination." "All right," says the doctor. "First let me ask you a few questions. Do you drink much alcoholic liquor?" "Have never touched the stuff," Doc," answers the patient.

"Ever smoke?" "Never started the filthy habit," he answers. "Do you run around nights?" "No," answers the patient. "I'm always in bed by ten o'clock."

"Let me ask you one more question," says the doctor. "Do you ever have sharp pains in your head?"

"Yes, I do," said the examinee, "that's what I have been worried about. I often get pains in the top of my head and sometimes a sort of a kink."

"There's your whole trouble," said the doctor. "Your halo is on too tight."

COLLOIDAL IRON

VS

IONIZABLE IRON

IN THE MOUTH

WHILE orally administered iron is absorbed from the intestine, the entire alimentary tract is by anatomical necessity subjected to its influence. Thus the problems of irritation, of staining, of dehydration, and other unpleasant side reactions have become the bugbear of hematonic therapy. There are, however, significant differences between the iron salts and colloidal iron, which are of major importance in this connection. The iron salts (sulphates, citrates, etc.) ionize more or less readily with the liberation of acidic ions. And it is to this chemical fact that many of the unpleasant side reactions of iron administration are attributable. In the mouth, for example, the iron salts may dissolve tooth enamel

may stain, are unpalatable and unpleasant. But these things are not true of OVOFERRIN, for OVOFERRIN is colloidal iron in its most minute, most efficient subdivision. It is not in ionizable form. It cannot stain or dissolve tooth enamel any more than an iron nail can. It is tasteless, odorless, and pleasant to take, thus assuring patient cooperation. Yet OVOFERRIN is highly assimilable since it is in the colloidal state, the form in which most foods are physiologically absorbed. As it is fully hydrated, it cannot cause dehydration and constipation. In over 39 years of widespread use it has earned the title of 'the rapid blood builder.' Prescribed in 11 ounce bottles; one tablespoonful at meals and bedtime in milk or water.

OVOFERRIN

COLLOIDAL IRON BLOOD BUILDER

in Secondary Anemia, Convalescence, Pregnancy,
the "Pale Child" and Run Down States

LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York

Responsibility of Physician for Acts of Nurse

VERY recently in a nearby jurisdiction a decision was handed down by an appellate court involving the liability that may be imposed upon a physician by a nurse not in his actual employ.

The plaintiff in the case sued a Doctor A for damages for personal injuries alleged to have been sustained by her as a result of medical treatment by the defendant.

Upon the trial the proof established that prior to July 1, 1936, Doctor A had been practicing his profession as an employee of Doctors B and C, who were partners, and that on that date Doctor B left the partnership and Doctor A entered the partnership with Doctor C in place of Doctor B. The action was brought by the plaintiff against Doctor A individually and not against either of the two partnerships.

Plaintiff, upon the trial, established that prior to June 29, 1936, she had been treated as a patient for sinus infection and had received certain injection treatments at the office of the partners B and C. The facts upon which she relied in the case transpired on a single date, but she was entirely uncertain as to whether that date was June 29 or July 2.

Her testimony was that on the said day she called at the office and found Doctor A in charge and no other physician present. She asked him for further medical care, and he referred her to a nurse in the office with instructions that an injection of omnadin be given. That nurse, so far as appeared, was qualified. She, however, turned the patient over to "a girl in blue," who seems to have been an office attache ordinarily charged with minor nonmedical duties. Plaintiff testified that the latter girl administered an injection that caused the injuries complained of. According to her, a rather dirty appearing tray or pan was produced containing a bottle in which was a hypodermic needle. On former occasions injections had been made of substances withdrawn by a sterilized needle from a sealed ampule. There was no sealed ampule in use on the date in question. As the injection was made the plaintiff evidenced some unusual pain and "the girl in blue" placed her hand over the spot where the needle was inserted. An infection causing some disability and suffering followed the incident.

Upon such proof the plaintiff recovered a verdict at the trial against Doctor A. He appealed, however, and upon that appeal the Court of Appeals reversed the judgment and entered judgment in favor of the defendant doctor.

The first point that was taken into consideration was that of the status of Doctor A, that is, whether he was an employee of B and C, partners, or whether he was a partner of C. The Court of Appeals ruled that since the burden

was upon plaintiff to establish facts imposing liability upon Doctor A, her evidence had to be considered as establishing that the date of the treatment was June 29, a date when Doctor A and "the girl in blue" were fellow employees of the partners B and C.

The Court of Appeals ruled that under such circumstances no cause of action against Doctor A had been shown and said in part:

"As Doctor A was still an employee of Doctor B (and Doctor C), and the nurse and 'the girl in blue' were also employees of Doctor B (and Doctor C), the effect of this action is to attempt to charge one employee with the negligence—if any existed—of a fellow employee. No rule of law has ever imposed liability under such circumstances.

"It is claimed that a physician, though merely an employee, has some unassignable obligation which imposes upon him liability for the acts of his fellow employees in a physician's office.

"No controlling authority is cited in support of this claimed exception to the general rule.

"It is asserted that the plaintiff is helpless in the presence of such a situation. Such is not the case, for the employer is responsible for the negligence of any of his employees. That the plaintiff has mistaken the responsible defendant—if negligence and proximate cause were proved—is beside the point. It is clear that the plaintiff having failed to prove any direct liability on the part of the defendant for the acts of which she makes complaint, the judgment of the Court of Common Pleas should be reversed and judgment here entered for the defendant."

Inquiries

YOUR Counsel recently received the following inquiry:

"Dear Mr. Brosnan:

"As Counsel for the State Medical Society, would you be willing to give me an opinion on the following point:

"Patient A is injured in an automobile accident, following which he has an x-ray examination at the request of his attending physician. Patient A then sues the man whose car struck him.

"Sometime later the court action is instituted and the patient is examined by another physician who is paid by the defendant in the action.

"When patient submits to the examination by the second physician, by such action is there an implied understanding that the physician representing the defendant has a right to see any and all x-rays taken with reference to the accident?

Sincerely yours,"

[Continued on page 405]

* Rath vs. Craddock, 29 N.E. (2nd) 426

Simply to remind you why Horlick's Malted Milk enjoys physicians' confidence

FADS come and go. Doctors are besieged with "samples" and "literature." Yet an amazing preponderance of the medical profession goes calmly along, relying on Horlick's Malted Milk.

Here are two fundamental reasons —

1. By long clinical use, Horlick's has proved its value in feeding infants, growing children, ill, convalescent and well adults, the aged.
2. Horlick's contains sound, basic nutritional factors—the well balanced protein of milk and wheat . . . fat in the form of genuine butterfat, derived from full cream milk, combined with the lactose of milk, and other carbohydrates . . . enzyme processed for ease of digestion

In cases where you want to prescribe a scientifically conceived, thoroughly established milk-cereal food, specify Horlick's Malted Milk, natural or chocolate flavor. All druggists carry it

HORLICK'S MALTED MILK CORPORATION
RACINE, WISCONSIN

[Continued from page 403]

Your Counsel's reply was as follows

"Dear Doctor

"In your letter you inquire as to whether, when a physical examination is arranged for the benefit of the defendant in a personal injury action, there is an implied understanding that the examining physician is entitled to see any and all x-rays taken with reference to the accident

"Unless the plaintiff's attorney consents the examining physician for the defendant cannot compel the production of prior x-rays

"In a proper case the defendant may procure an order from the court requiring that a plaintiff in a personal injury action submit to x-ray examination in order that his true physical condition at the time of the examination may be ascertained

Very sincerely yours,"

Your Counsel recently received the following inquiry

"Dear Sir

"Yesterday I was called to see A, 11 years old, who is boarding with people in C. I found that he had appendicitis and decided that an immediate appendectomy was necessary

"A's mother and father are separated and the mother has custody of the children. It was very difficult to reach the mother to get her consent to operation, and five hours passed before she was found. If she had not been located would we have made ourselves liable to a malpractice suit by operating without consent?

"The operation was successful and we look for a speedy recovery. However, accidents do happen sometimes, and I would like to know just how much liability we would incur by operating on a minor without the guardian's consent.

"Dr W is physician to X Military Academy and some of the pupils are from Panama and South America. It is possible that one of them might be stricken with an ailment requiring surgical operation. What would be his standing if he were unable to locate the guardian to obtain consent?

Yours truly,"

Your Counsel's reply was as follows

"Dear Doctor

"I acknowledge receipt of your letter in which you make certain inquiries concerning the necessity of a consent to operate in various cases involving infants

"The principal case cited by you in your letter was one in which an eleven-year-old child, one A required an immediate appendectomy. I believe that you would not have made yourselves liable to a suit for damages if you had proceeded with the operation without actually obtaining the consent, since you did, in fact, make a reasonable effort to obtain the consent of a parent of the child and since the case was one in which an actual emergency existed requiring the operation in an endeavor to save the patient's life

"In general, it may be stated that where no actual emergency exists requiring immediate operation to protect the life of an infant patient, no operation may be performed without the consent of at least one of the parents or the legal guardian of the child.

"I understand that in X Military Academy some of the pupils are from Panama and South America and that Doctor W seeks suggestions as to procedure when one of the pupils of said Academy might be stricken with an ailment requiring surgical operation. In every case where no emergency exists, I believe that no operation should be undertaken without first obtaining consent by cablegram from the parents. Where an emergency exists I feel that wherever possible the parents should be cabled and their consent requested in order that a reasonable attempt be made before operation to obtain actual consent of the parents. However, in an extreme emergency where it appears that consent by cable could not be obtained in time for the operation, I would suggest that the best procedure would be for the doctor in charge of the case to notify the principal or headmaster of the school of the circumstances and obtain his consent to operate as the person charged in such cases with responsibility for the welfare of the pupil

Yours very truly,"

BASKETBALL OVERTAXING ADOLESCENTS

The Journal of School Health returns to its criticism of our too strenuous basketball and notes that physicians, health officers, coaches, and sports writers have taken a stand against the present rules. The game is too strenuous, probably, for college players, unless the squad is large enough to permit frequent substitution, and it is certainly detrimentally strenuous for adolescent boys—high-school players

Since only the rule makers seem to favor the present rules, it devolves upon those who are truly interested in the physical welfare of boys to bring pressure upon these rule makers to compel them to adopt changes that will give more opportunity for "breather" periods, so that the circulation may have greater opportunity to

remove the waste products of vigorous exercise and thereby to lessen the strain on the heart

Not only is it a matter of common observation by those who witness games that the game is too strenuous, but reports from physicians, based on actual examinations and studies, show that the present rules result in chronic increased blood pressures and other evidences of serious harmful results

Every school physician, health officer, and school administrator should insist upon modification. Failing to get modification, the high schools themselves should adopt a set of rules of their own. There is no sensible reason why secondary school athletics should follow humbly at the heels of college athletics

PRESENTING

KARO SYRUP IN

GLASS!!

1½ LBS NET

The history of Karo is inscribed in the nutrition of millions of infants. It reveals universal acceptance of Karo Syrup as an excellent source of dextrins, maltose and dextrose. Karo remains the effective milk modifier for all forms of milk and for every type of infant feeding problem.

The composition of Karo cannot be improved, so it is now introduced in superior containers—in streamlined glass bottles. Karo Syrup is processed at sterilizing temperatures and sealed hygienically in these sparkling glass containers.

The high sanitary quality of Karo can now be maintained while using the clear glass bottles in the nursery or kitchen in the preparation of infants' formulas.

The cost of 24 ounces of Karo Syrup in glass bottles is only slightly more than in cans. Karo thus yields (volume for volume) double the caloric value of powdered maltose-dextrins-dextrose at a fraction of the cost.

Karo is bacteriologically safe, devoid of laxatives or any impurities, well-tolerated by newborns, infants and children, easily digested even in difficult feeding problems, absorbed by gradations at spaced intervals in the intestinal tract, prevents flooding of the bloodstream with exogenous sugars.

CORN PRODUCTS SALES COMPANY

17 Battery Place, New York City

KARO IS, OF COURSE, STILL AVAILABLE IN THE FAMILIAR SANITARY TINS

Say you saw it in the NEW YORK STATE JOURNAL OF MEDICINE

Public Health News

AT THE section meeting for school physicians, held on December 26 at the Hotel Syracuse, Dr O W H Mitchell, chairman of the Committee on Public Health and Education of the Medical Society of the State of New York, presented a paper entitled "Legislative Activities Regarding School Health Service." He mentioned the recent development of what is called medical inspection and school health service and the rapid progress which has been made. What activities should be included in such a service are not easy to determine. In keeping with the policies and principles that determine our form of government, we face the problem of doing too much as well as doing too little. Experiences in other countries should caution us to do things well—not attempt too much and avoid rapid expansion.

Criticism of the school health service has largely resulted from a lack of adequate provision preceding operation of activities. Medical schools and schools of education have failed to include in their curriculum courses that are necessary in the preparation of physicians and teachers who assume the responsibility of school health service and health education. This weakness in education is now being corrected.

Dr Mitchell also referred to the action recently taken by the Medical Society of the State of New York regarding the need for a special school health division devoted entirely to health and medical problems as a part of the State Department of Education or the State Department of Health. At the present time these activities are combined with physical education.

The physicians believe that such a reorganization would strengthen both the school health service and physical education activities. These suggestions were adopted as resolutions by the House of Delegates of the State Medical Society and have been presented to Commissioner Cole of the State Department of Education and Commissioner Godfrey of the State Department of Health.

It was called to the attention of the school physicians that the Medical Society has a special committee on School Health Service. The members are Dr E C Wood, White Plains, Westchester County, chairman, Dr Albert D Kaiser, Rochester, Monroe County, and Dr A C Silverman, Syracuse, Onondaga County. This committee will gladly meet with representatives of other groups for discussion of school health activities and policies.

Dr Michael Levitan, school health director, Rome, New York, spoke on "The School Physician's Part in National Preparedness."

"Defense from the health and life angle is as old as life itself. Health is a means of protecting the individual or group against affliction or disease and is traceable to the distant past."

"Today, with the appreciation of the effectiveness of modern methods of prevention and scientific sanitation, health measures are considered definite means of defense when our country is threatened with the spread of the war from the other side of the ocean."

"Since school health functions have for their objective the protection and preservation of the health, growth, and proper physical and mental development of our boys and girls, health service, health education, and guidance are basically significant at this time of national concern. Education in general and health education in particular are the very cornerstones and foundation of the nation and, together with proper administration, constitute the first line of national defense."

"Proper health education is a powerful and vital factor leading to the proper control of muscle and brain. As a preparedness measure we need in number and in efficiency more teachers of health education, school physicians, nurse-teachers, dentists, dental hygienists, physical training instructors, and mental hygienists."

"In the field of school health the school physician has a very important and entrusted post equal in responsibility to that of the army medical officer. While the duties of the school physician are of a different character, they are no less vital. He has the ardent task through preventive means and health education of keeping the young and growing school children under his administration physically and mentally fit to face the hardships and fight the battles of life after they leave school."

"Upon his shoulders rests the duty of aiding and assisting the school children to overcome their deficiencies of nutrition or defects of posture, tonsils, glands, teeth, and hearing. He must also aid in the problems of behavior. He must take particular pains with those children whose lot it is to have congenital or acquired abnormalities of heart or limb. In many instances such conditions may be prevented. The removal of diseased tonsils and timely care of dental caries lessen the chances of rheumatic fever in childhood and any resulting cardiac damage. Nor should it be forgotten that proper supervision and guidance of children afflicted with post-rheumatic or postpolio conditions may help restore these children to normal life."

"The advantages of health service, health education, and physical training in the schools during the past twenty to twenty-five years, through absorption of health knowledge and practice, must have had at least some effect upon the development of our boys into manhood."

"A report of the Metropolitan Life Insurance Company says in part: 'Even in advance of detailed findings on medical examinations it is safe to predict that the draftees will be found to be healthier, better developed physically and with a lower incidence of serious impairments than the draftees of 1917-18.'"

"There is no better investment for the city, state, nation, and individual taxpayer than money expended on the health of school children. The very strength of our republic depends upon the health of the school children, out of whom is built the nation's manpower in muscle and brain. Health is mainly a medical problem and it is the part of the school physicians and other health workers to make it the foundation of the nation's strength."

Woman's Auxiliary

To the Medical Society of the State of New York

THE New York State Medical Society Convention will be held in Buffalo, April 28 to May 1, inclusive. At this time the Woman's Auxiliary holds its annual meeting at the Hotel Statler. Make your reservations now. Worth-

while medical information, pleasant social functions, and renewed friendships are in store for you. All doctors' wives are invited and information may be obtained from Mrs. Carlton E. Wertz, chairman, 95 Parker Ave., Buffalo.

County News

First we present the newly formed group, Niagara County. On October 18, 1940, with the permission of the county medical society, forty-five doctors' wives met at the Hotel Niagara for a luncheon meeting. They chose as their leaders president, Mrs. W. R. Scott, first vice-president, Mrs. W. D. Leone, second vice-president, Mrs. F. W. Barry, recording secretary, Mrs. E. F. Dodge, corresponding secretary, Mrs. M. S. Cohen, treasurer, Mrs. J. Kingley, directors, Mesdames H. V. Cramer, G. Guillemont, and R. P. Regan. At the November assembly the Constitution and Bylaws were adopted. In December at a round-table luncheon gathering, Dr. Carl Lathrop of the Niagara County Tuberculosis Association addressed the members and showed interesting movies. On January 7 the new president of the county medical society explained the aims of a medical organization. A genuine spirit to further kindly feeling among doctors' wives has been demonstrated by the increased total to seventy-four members. *Good wishes for your continued success in this worthwhile undertaking.*

Cayuga. The annual dinner with the Cayuga County Medical Society took place recently at the Osborne Hotel. Justice Benn Kenyon related the associations of "Medicine and Law" to the delight of everyone present. A business meeting was conducted by Mrs. G. Sincerbeaur. The Red Cross asked for more help from the auxiliary. Mrs. Alfred K. Bates is chairman of a committee to investigate the advisability of the group working for the Bundles for Britain, Inc.

Columbia. The fourth annual luncheon and business meeting convened at the General Worth Hotel in Hudson, Mrs. Wm. D. Collins presided. Nine meetings were held during the past year. Outstanding speakers were Mrs. A. VanderVeer, Dr. Marion Loew of the State Department of Health, Mrs. H. E. Raney, and Mr. John Hoysradt, monologist. Newly elected officers are president, Mrs. R. L. Bowerhan, president-elect, Mrs. H. G. Henry, first vice-president, Mrs. L. J. Shonk, second vice-president, Mrs. Chas. Nichols, treasurer, Mrs. R. F. Spencer, recording secretary, Mrs. H. G. Pattison, corresponding secretary, Mrs. L. M. Miesen.

Erie. Celebrating in December their first anniversary as an auxiliary, two hundred physicians and their wives marked a memorable event with an enjoyable dinner party in the Terrace Room of the Hotel Statler. Much credit for its success is due to Mrs. Patrick Hurley, general chairman, and her able assistants. A round table luncheon preceded the business session on December 17 at which Mrs. C. E. Wertz was unanimously elected president for the second year.

Other officers are first vice-president, Mrs. P. J. Hurley, second vice-president, Mrs. S. L. Walczak, recording secretary, Mrs. H. B. Johnson, corresponding secretary, Mrs. A. E. Richter, treasurer, Mrs. J. D. Naple. Fifteen delegates were chosen to the New York State Medical Convention. After the reports there was a musical program in charge of Mrs. F. N. Potts. The efforts of the Erie County auxiliary are turned toward the convention meeting for which they are to be hostesses.

Kings. January 19 found the members of the auxiliary on their way to the National Broadcasting Company to enjoy the program "Alma Kitchell's Streamline Journal." Mrs. Louis Harris, president, has announced the February meeting to introduce Mrs. Lewis Paddons who will speak on "The Motion Picture Council." In addition, Mrs. Chester A. Peake will give a book review.

Montgomery. The December meeting at the Amsterdam City Hospital had as guests Dr. S. L. Homrighouse, Dr. P. J. Fitzgibbons, Dr. Philip B. Barton, and Dr. Leonard M. McGuigan, members of the advisory council. Dr. Homrighouse, then president of the Montgomery County Medical Society, welcomed the women to a society which is 135 years old. Dr. Fitzgibbons spoke on health "not being a police duty but rather an educational program." Dr. Barton spoke on the friendliness of the society and what it can accomplish. Dr. McGuigan presented the auxiliary with a check for \$10 contributed by the county medical society. Following the session, tea was served. Dr. Julius Schiller was the speaker at the January meeting. In the course of a brief address, the newly elected president of the medical society assured the auxiliary members of the society's cooperation in their work. Mrs. S. L. Homrighouse, president, conducted the business meeting at which plans were made for a dinner party to be held February 13.

Nassau. Nassau County had the honor to have as their distinguished guest the president of the American Medical Association, Dr. Nathan B. Van Etten, at the celebration of their fifth anniversary on January 28. The meeting was preceded by a dinner and a brief business session, conducted by Mrs. A. C. Martin, at the Garden City Hotel. Dr. Van Etten was introduced by Mrs. L. H. Kice, state president.

Queens. Twenty-five were present at first of a series of "Membership Teas," held at the home of Mrs. Harold Foster, 34-07 103 St., Corona, on January 21. Three new members were presented by Mrs. Edwin Core, of Forest Hills, membership chairman. Tea was poured by Mrs. Michael M. Schultz, president. All had a very enjoyable afternoon.

**DON'T JUDGE THE WORTH
OF THIS *Portable*
X-RAY UNIT BY ITS SIZE**

USE the G-E Model F-3 Office-Portable X-ray Unit seems so small in size, and its moderate, don't overlook its practical range and its ability to produce films of high quality

The Model F-3 is a unit that you can rely on for satisfactory, dependable x-ray service within its range—in your office or at patient's bedside—wherever adequate roentgenological service is not otherwise available

What a valuable assistant the F-3 could be. Why not do as hundreds of value-wise hospital men did? Judge the F-3 strictly on performance. See this fine unit right in your office. Then you can actually use and handle the F-3 just as you would in your daily practice. And you'll get first-hand information about its refined, simplified control and its total flexibility

So all you have to do to arrange for this interesting demonstration. Just clip, sign, and mail the convenient coupon, today. We'll do the rest.

CLIP, SIGN, and MAIL, TODAY.

I'm interested in an actual working demonstration of the G-E Model F-3 Office-Portable X-Ray Unit. When next in this vicinity, please have your representative arrange with me for a time most convenient to me

MAXITATE

*The Longest Acting
Vasodilator of the*
5-6 Hours

Nitrite Group

THE SUPERIORITY of Maxitate lies in the fact that its action persists longer than any other vasodilator of the nitrite group. With proper regulation of dosage the initial period of vasodilation, 5-6 hours, may be prolonged considerably. The action of Maxitate is beneficial to patients because there is no sudden reduction of pressure with accompanying ill effects, instead the action is gradual.

REVIEWED

Diabetes Practical Suggestions for Doctor and Patient. By Edward L. Bortz, M.D. Second edition. Octavo of 296 pages, illustrated. Philadelphia, F. A. Davis Co., 1940. Cloth, \$2.50.

The author has revised the material in this second edition and has brought it up to date so far as recent advances in diabetes are concerned. It is a well-rounded monograph, written in clear and simple style, and should prove useful to the patient suffering from diabetes. The reviewer finds it necessary to call attention to several aspects of the presentation which would prove misleading to the patient. For example, the color chart illustrating the approximate quantitative content of glucose in the urine based upon the qualitative test is not correct. A complete reduction of the copper solution occurs when 2 per cent or more of glucose is present. It is impossible above that concentration to determine its content with a qualitative analysis. Further, the statement that the dose of insulin in juvenile diabetes is based on the age of the patient is incorrect. No one who has had experience with diabetic juveniles would be willing to accept this statement. The dose of insulin depends entirely upon the severity of the diabetes, regardless of the age.

WILLIAM S. COLLENS

Heart Failure By Arthur M. Fishberg, M.D. Second edition. Octavo of 829 pages, illustrated. Philadelphia, Lea & Febiger, 1940. Cloth, \$8.50.

It is a great pity that Fishberg thought it necessary to add forty odd pages to the latest edition of his excellent book, *Heart Failure*. The new material is doubtless worthwhile, but the additional bulk will not make the volume more attractive to students and practitioners. The vast majority of readers are not particularly interested in reading too detailed abstracts of literature, particularly if after plodding through such abstracts they are told that much of the work has been disproved.

The book as it stands now is an extraordinarily able digest and interpretation of a vast amount of material. No one can take issue with the choice of sources nor with the just appraisal, but it is unnecessarily verbose.

New material has been added to velocity studies, paroxysmal dyspnea, the picture of left and right heart failures, as well as to other chapters.

ANDREW M. BABBY

The New International Clinics. Original Contributions, Clinics, and Evaluated Reviews of Current Advances in the Medical Arts. Edited by George M. Piersol, M.D. Volume III, New Series Three. Octavo of 358 pages, illustrated. Philadelphia, J. B. Lippincott Co., 1940. Cloth, \$3.00.

Some of the original communications are those on peptic ulcer, analysis of emotional factors in coronary disease, Mikulicz disease, and accidental injuries in office practice.

Cutler presents a valuable article on the "Present Concept of Erythrocyte-Sedimentation Rate." He describes a technic that completes the test in thirty minutes using a Cutler tube and a graph to show the most rapid drop in millimeters in any five-minute interval. This is the maximum sedimentation rate. Normal standards and the interpretation of abnormal rates are given.

There are clinics from the Cornell University Medical College and the New York Hospital, on twelve topics. Heuer points out the advantages of early diagnosis and treatment in gallstone disease from a study of 1,142 patients.

A review of ten years' progress in obstetric analgesia from The Johns Hopkins Hospital should be of much interest to obstetricians, as it is nicely presented by L. M. Hellman.

W. E. MCCOLLUM

Public Health Administration in the United States. By Wilson G. Smilie, M.D. Second edition. Octavo of 553 pages, illustrated. New York, The Macmillan Co., 1940. Cloth, \$3.75.

This book first appeared five years ago and now in its second edition is brought up to date. The expansion in the field of medicosocial work during the past five years is notably evident in the growth of public interest in national health affairs. The development of the national health program is reviewed by Dr. Smilie.

Increased knowledge concerning the epidemiology of disease enables more definite control measures to be applied to the communicable diseases. The usual basic activities of a public health organization are considered, particular attention being given to the newer knowledge with respect to nutrition. It is gratifying to note the increased recognition of nutritional problems as a phase of public health work.

This book is of interest primarily to public health administrators, but the private physician will find much that is of direct concern to him in his everyday practice.

A. E. SHIPLEY

Clinical Electrocardiography. By David Scherf, M.D., and Linn J. Boyd, M.D. Octavo of 362 pages, illustrated. St. Louis, C. V. Mosby Company, 1940. Cloth, \$6.25.

The authors state in their introduction that they have undertaken to write the present volume because many recent books on the subject have devoted themselves to the main essentials of the subject and have created the impression that electrocardiography is extremely simple.

Books

[Continued from page 411]

Those thoroughly acquainted with the subject realize that this is not so and that many erroneous diagnoses follow this impression

The book is designed for those who have passed the beginner stage and draws attention to many variations that can take place in both normal and abnormal tracings. All the important phases of the subject are discussed and various theories analyzed. Because of the importance that coronary disease has assumed, it seems as though more space could have been devoted to this. Other subjects of possibly less importance have been much more exhaustively dealt with. A critical discussion of disputed points is given, and no extreme view seems to be taken. A bibliography is attached to each chapter so that original articles may be consulted if desired. The printing and figures are excellent.

Altogether this volume seems to have accomplished its purpose and is a good addition to electrocardiographic literature

J HAMILTON CRAWFORD

Physical Diagnosis. By Ralph H Major, M.D. Second edition. Octavo of 464 pages, illustrated. Philadelphia, W B Saunders Co, 1940. Cloth, \$5.00

The second edition of Major's *Physical Diagnosis* is an improvement on the first which means that it is a good book indeed. The peculiar virtues of Major's treatment of his material are still much in evidence. The historical approach, numerous citations of classic descriptions, abundant and well-chosen photographs, and, above

all, the omission of irrelevant chapters on x-ray, electrocardiography, and laboratory diagnosis which burden other similar books are worthy of praise. Recent innovations in physical diagnosis, such as Reich's method of enhancing tactile fremitus, are included. Major may be enthusiastically recommended by all teachers of the art.

MILTON PLOTT

Atlas of Cardio-roentgenology. By Hugo Roesler, M.D. Folio of 124 pages, illustrated. Springfield, Charles C Thomas, 1940. Cloth, \$8.50

This is a painstaking summary of a fairly wide cross section of cardiac pathology, correlating anatomic findings together with clinical, electrocardiographic, and roentgenologic examinations. Studies of postmortem findings and their relationship to roentgenologic data form the most valuable part of the book. Cross sections of the heart and great vessels in various planes furnish an excellent foundation for orientation so necessary in the interpretation of roentgenologic examinations.

The material in the book covers a generous variety of types of cardiac pathology, examples of early changes, as in aortitis, might add to its value. It is to be regretted that an index was not included. In the reviewer's opinion this would enhance its value as a reference work.

The author is to be congratulated for his careful and concise contribution to the study of cardiology

Hospitals and Sanitariums

Institutions of Specialized Treatments

UNWILLING GUESTS*

A follow-up letter mailed by a hospital director to a discharged patient, rather uniquely referred to patients as "unwilling guests." If this letter had not been a masterpiece of good will and good business otherwise, we might have said the phrase was really in bad taste.

If the director meant, as he may have intended, that patients of all hospitals and sanitariums are unwilling guests, we can find many reasons to differ with him. If he merely intended it for his own institution—the letter expressed it "our unwilling guests"—then perhaps we have no right to criticize his judgment. Yet, knowing his hospital to be one of the most modern and efficient, we can't console ourselves in classing it with an institution for reform. As we understand opinions, only prisons are generally considered as having "unwilling guests."

Granted the normal being prefers to view hospitals from the exterior, men and women in severe pain or with no other alternative for saving their lives or limbs, or sight, certainly must be willing to enter a hospital. If during convalescence, acute nostalgia becomes a serious symptom and creates an unwilling guest, it is largely because the hospital is not equipped to compete with "home sweet home."

In this respect, the private sanitarium has an edge. The rather trite phrase "homelike atmosphere" that distinguishes sanitariums is not as ambiguous as it may sound, for almost without exception the buildings, furnishings and surroundings are reminiscent of a private residence.

Of course this may not make a sanitarium a "vacation resort" for even the sick, but it hardly makes the patient less "willing" to be nursed back to health. Unlike hos-

pitals maintained more specifically for medical and surgical emergencies, the sanitarium must essentially provide more in comfort and diversion, for its guests are less transient and ordinarily require longer periods of routine nursing and treatment.

Fortunately, when deciding upon a sanitarium, a

physician has more time to select a place best suited for his patient than he has when selecting a hospital for an emergency, and he can as the saying has it "look around a bit" before making a recommendation.

And about the best place to begin "looking" is here in this department of your JOURNAL.

THE MAPLES INC., ROCKVILLE CENTRE, L. I.

A sanitarium especially for invalids, convalescents, chronic patients, post-operative, special diets and body building. Six acres of landscaped lawns. Five buildings (two devoted exclusively to private rooms). Resident Physician. Rates \$18 to \$35 Weekly.

A Guide to Select Schools

SCHOOLS OF REFINEMENT WITH HIGH RATING IN EDUCATIONAL AND CULTURAL ADVANTAGES

"SCHOOL MEDICINE"

A friend suggested that his neighbor consult the family's physician about "special education" for one of the children. The parent retorted, "Why should the doctor be interested in education for my children, or in getting business for some private school? It's no money in his pocket."

To which the friend's rebuttal might have been, "No, but neither is the medicine that his prescription obtains for you at the pharmacy."

* * *

Many parents have still to learn that the family physician's part in educational guidance is more than just a friendly interest or "good business"—that it is even more than a self-imposed duty. They should be informed that the doctor's share in "special education" is a part of the therapy in treating most cases of so-called "exceptional children," and—that the family physician is generally the best qualified person to prescribe the "special education" required.

* * *

Under the heading "schools," the medical profession has other concerns as well as prescribing the proper sphere of welfare for handicapped children. If the medical practitioner watches this section of the JOURNAL,

CAPABLE ASSISTANTS

Our free placement service will be glad to help you select exactly the right assistant. Paine Hall graduates are girls of character, intelligence, appearance—thoroughly qualified to assist in office and laboratory, trained in haematology, blood chemistry, urinalysis, clinical pathology, medical stenography, bookkeeping. Address inquiries to C. R. Porter, Principal.

VOLUME 41

MARCH 1, 1941

NUMBER 5

Editorial

"When We Meet Again"

April 28 to May 1, 1941—Buffalo The occasion, the annual meeting of the Medical Society of the State of New York. It is not too early for our members to set aside the time for their attendance this year. In view of the many grave questions and problems that confront the medical profession in the coming year, it is more than ever necessary that every physician who can do so should plan to attend, and to listen to the debates and deliberations in the House of Delegates. Only so can widespread understanding be acquired by the profession of the situations with which it is confronted. Already a huge army is in the making. Extraordinary problems in safeguarding the public health and welfare are arising daily. Large sections of the population are on the move to provide labor for the construction of vast new plants, cantonments, and public works.

New methods of treatment, new drugs and procedures will be discussed in the scientific sections as formerly. Expanding industry is creating new demands for men interested in the knowledge and technique of industrial hygiene. The operation of the now numerous plans for medical expense indemnity will be discussed. There are also new vistas being opened in the matter of physical and mental rehabilitation work in the state. New and more vigorous attacks upon the tuberculosis control problem are already under way. No matter what your interest is in the field of medicine you will profit by

attendance. And at the same time you will contribute by your presence to the steadily growing attendance at the meetings, this healthy growth is evidence to all of the vigor and vitality of your Society.

The scientific exhibit will be an education and an added stimulus to many. The war, lack of shipping facilities, and other economic factors have reduced imports of foreign-made goods. The challenge has been met by our manufacturers in many new and novel ways. We can assure you even at this early date that you will not want to miss the scientific exhibit which we hope will be larger and better this year than ever.

Section chairmen and committeemen have been concerned to present a program of outstanding merit. And while it is premature to write this early of details, they will shortly be published in full in the JOURNAL (April 1 issue). We are assured of the presence as a speaker at the banquet of Dr. W. W. Bauer known to many of you by voice at least as the commentator on the Wednesday night radio program of the A. M. A., "Doctors at Work."

The Women's Medical Society of the State of New York and the Woman's Auxiliary will meet at the same time. A record attendance is hoped for. When so much of importance is going on at Buffalo, when so much of vital concern to your professional welfare is being there transacted, can you do less than assist and

minorities, and it has been the function of medical education properly to qualify and discipline physicians to exercise their special gifts and skills. Their postgraduate life and activity is continuously governed by and subject to those disciplines.

Recently we have seen in Europe, and today are beginning to observe here "astride our times like a colossal giant," a curious manifestation of democracy, a belief on the part of the crowd, the aggregate mass, that it has the right to impose and to give force of law to any notions which may occur to it in the course of the day. Call it public opinion if you will, or anything else you choose. It does act, and does impose, within or without the law, its wishes, the notions of the multitude. Slowly it has begun to supplant the minorities, to override them, to crowd them out, to overbear them without benefit of the disciplines which have been the minorities' minimum requirements for competency. Perhaps it is a phenomenon of the degeneration of the democratic principle. But whatever it is, it is here.

What will be its effect on medical education? The human material with which medical education deals has changed somewhat in the last quarter-century. In the secondary schools and colleges the increasing tempo of life has left little time

to do more than to instruct the people in the mere technique of modern life, there has been no time to educate them. They have been, shall we say, "inoculated with the pride and power of modern techniques and instruments," but of their roots and spirit they know little and care less. There is a virgin world in which they walk with pride and arrogance, with a consciousness of mass power because they know the technique of modern living and little else. This is the human material upon some of which the institutions of medical education must impose the iron disciplines of its traditions. To instill these disciplines in the past has required much time even with culturally better prepared human material. What of the future?

Public authority is in the hands of the representatives of the masses of the people. It is sensitive to the developing stresses both social and economic within the now global revolt of those masses in this developing democracy which are impatient for power and intolerant of anything which does not move at the same speed, intolerant of anything which seems to be stationary or retrogressive, which seems tied to the past and to exercise therefore counsel of negation.

What future does this portend for medical education? And for medical practice?

Radio

It is of the utmost importance that the medical profession be continually in direct communication with the public it serves. This may sound strange to those who think of physicians as being always in communication with their patients, and even to physicians, who daily see and treat thousands of people. But a moment's thought will reveal that these thousands are only a small fraction of the public—and sick people at that. Therefore, the communication of individual physicians with that fraction of the public with which they come in contact centers largely about the disease or ailment from

which the individual seems to be suffering.

But physicians and the public have more to say to each other than that. It may not always have been so, but it surely is true now. There is that vast portion of the public which, usually in good health and spirits, does not know the physician, does not know what he is thinking about, does not realize the problems that confront him in his appointed task, does not know him as another human being. Medicine today is a cooperative effort as well as an individual skill. And it is fortunate that the

encourage your officers, your delegates, and your exhibitors by your presence? You make the success of the meeting Come one, come all!

Must Medical Education Be Revised?

A fluid American democracy under whatever political label you wish to put upon it seems now to be on the move in a direction which will involve, among other things, a more radical redistribution of economic wealth and power. What will be its effect upon medical education? We are already beginning to see some of its effects upon the current practice of medicine. Will medical education in general have to be fundamentally revised in order that the future practice of medicine may fulfill the popular conception of its social obligations?

We shall indeed be fortunate if, in the turmoil of present preparation for national defense and afterward, the institutions of this moving democracy can fully retain their heretofore fluid character. A free medicine has flourished in this democracy as it has never flourished before. We have passed through a recent maelstrom of social changes together with modifications of our former political points of view. These changes have subjected all our institutions to unusual stresses. These stresses have produced changes that at one point have been accelerated, at another, retarded, and at still another, redirected. These changes have occurred simultaneously and concurrently within the recent years, testing the vitality and fluidity of the democratic way of life.

This way of life has, however, yet to be tested by the further impact of external threat. It is probable that this impact will further accelerate the rate of social and economic change. If we conceive of this progressive and yet evolving democracy as moving at a rapid pace it becomes at once apparent that the inherently slower pace of medical education and practice will appear against the more rapidly moving background to be halted or even retrogressive. It is doubtful whether this evolutionary pace of medical education and practice can be accelerated.

In the popular mind it will appear to be recessive or create the illusion, wholly fictitious, of rigidity and fixation at a moment when men's eyes and minds are concentrated upon the more dramatic, colorful, and rapid motion of our fluid and evolving democracy. In the same way a moving wagon wheel in the cinema with relation to the speed of the camera may appear to stand still or even to be going backward while the wagon itself is moving forward.

Medicine may thus appear to be reactionary and unsympathetic to social change and political progressivism. And in a world of turmoil and political flux few will have the leisure or the inclination to distinguish between the appearance and the reality. For in the larger sense the world of reality as many of us have known it no longer exists. The program of possibilities which constitutes our present life is tremendous. It has suddenly "overflowed all the channels, principles, norms, ideals handed down by tradition."¹ And the past has thus become but counsel of negation.

Certainly, medicine—by its own insistence and practice—constitutes one of the truly disciplined minorities in the body politic, and the character of its educational institutions has been formed by the necessary function which they exercise in carrying forward those disciplines and imposing them upon the profession. Such disciplines, evolved slowly in the past from the bitter realities of life and death, are the irreducible minimum of the educational function in medicine. There are in the social complex of human organization activities and functions of the most diverse order which cannot be carried out without certain special gifts and disciplines. These functions have been generally exercised heretofore by qualified

¹ *Revolt of the Masses* Ortega y Gasset. W. W. Norton, New York, 1932.

Immunization with Tetanus Toxoid

Since 1934 the medical staff of the United States Navy has used tetanus toxoid for active immunization of a large number of its personnel against tetanus. To date, no case of tetanus has appeared in those injected with the alum-precipitated toxoid.

The procedure described by Hall¹ is to give two injections, the second after an interval of eight weeks, to afford basic immunity. Every four years, thereafter, the toxoid is administered to maintain immunity at a high level. If an injury occurs in the interim, an injection is given to raise rapidly the blood antitoxin. The tetanus toxoid is preferably injected intramuscularly so as to reduce the soreness to a minimum and to eliminate cutaneous reactions which may be unpleasant. The recommendation that immunity is enhanced when the subcutaneous route is employed finds no con-

fimation in Hall's report, since the antitoxin titer was the same in cases where severe skin reaction occurred as in those where none was manifest. Immunity depends not so much on the blood level of antitoxin as upon the tissues' ability to produce antitoxin.

This large-scale study over a period of six years is an important addition to medical preparedness. Tetanus can now be added beside the many diseases against which the growing number of recruits are being immunized during their period of training. Many minor cuts or abrasions are overlooked by the soldier who is at all times exposed to infection with the tetanus bacillus. Immunity conferred by the alum-precipitated, tetanus toxoid will eliminate the cases of tetanus which result from carelessness or the inability to receive or administer antitoxin in time. There seems little doubt but that it will be universally adopted by the military services.

¹ Hall, W. W. *Ann Int Med* 14: 565 (1940).

American College of Surgeons to Hold Sectional Meeting in Pittsburgh

Surgeons, members of the medical profession at large, and executive personnel of hospitals in eight states and the District of Columbia will gather in Pittsburgh March 17 for a three-day Sectional Meeting of the American College of Surgeons. The participating states will be Pennsylvania, Ohio, Virginia, West Virginia, Delaware, Maryland, New Jersey, and New York. Headquarters will be at the William Penn Hotel.

Distinguished surgeons from all parts of the country will address the scientific sessions and lead the conferences and panel discussions. Among them will be the president of the College, Dr. Evarts A. Graham, of St. Louis, professor of surgery at Washington University Medical School, Dr. John Scudder, instructor in surgery, Rockefeller Institute for Medical Research, New York City, Dr. Frank E. Adair, attending surgeon at Memorial Hospital, New York City, Dr. Robert H. Kennedy, associate clinical professor of surgery, Columbia University, New York City, Dr. George P. Muller, of Philadelphia, past-president of the College, Dr. Alton Ochsner, director of the department of surgery, Tulane University, New Orleans, Dr. Alfred W. Adson, professor of neurologic surgery, Mayo Foundation, Rochester, Minnesota, Dr. Edwin C. Hamblen, associate professor of gynecology and obstetrics, Duke University, Durham, North Carolina, Dr. Emil Novak, associate in clinical gynecology, and Dr. John M. T. Finney, Jr., associate in clinical surgery, Johns Hopkins University, Baltimore, Dr. William E. Lower, director of the Cleveland Clinic Foundation, Cleveland, Dr. Robert S.

Dinsmore and Dr. Charles C. Higgins, the Cleveland Clinic Hospital, Dr. Fred W. Rankin, of Lexington, Kentucky, Dr. Roy D. McClure, surgeon-in-chief, Henry Ford Hospital, Detroit, Dr. Philip H. Kreuscher, associate professor of surgery, Northwestern University, Chicago, and many others from middle western and eastern states.

Operative and nonoperative clinics and demonstrations will be held each day of the meeting in the twenty-one hospitals in Pittsburgh approved by the American College of Surgeons. At the headquarters hotel there will be educational and scientific exhibits and showings of motion pictures portraying surgical and hospital procedures.

A hospital conference, also sponsored by the American College of Surgeons, will be held concurrently with the surgical meeting. New points of view on a variety of subjects of interest to hospital personnel will be presented by outstanding authorities in the hospital field.

On Wednesday evening, March 19, in Carnegie Music Hall, outstanding speakers on medical and health subjects will address the public at a Meeting on Conservation of Health under the sponsorship of the American College of Surgeons with the cooperation of the educational, scientific, civic, religious, and welfare organizations of Pittsburgh.

The Committee on Local Arrangements for the Sectional Meeting consists of Dr. Otto C. Gaub, chairman, Dr. Frank R. Bailey, vice-chairman, Dr. Nelson P. Davis, vice-chairman, and Dr. John W. Stanson, secretary. The chairman of the subcommittee on clinics is Dr.

radio now provides a means whereby the doctor and the public, the healthy public as well as the ailing individual, may discuss their common aims. More and more physicians are convinced of the necessity for direct communication with the public if the cooperative effort is to succeed and to keep pace with the tempo of modern times, if the common problems are to be fully understood, if the well public is to comprehend its friend and fellow citizen, the physician, in the framework of a common purpose and against the background of his professional activities.

The progressive physician of today welcomes the radio—as he did the telephone not so long ago—as another means whereby he may better serve the public interest, not alone the interest of the sick but also the interest of the healthy. That is the reason why the Medical Society of the State of New York, at the instigation of a forward-looking House of Delegates in 1940, has been intensively studying the question how the profession and the

public may best collaborate in obtaining a comprehensive and fruitful discussion of our common problems and objectives.

For the problems and objectives of the citizen-physician and the public are the same. Yet often the language of the physician and that of the public differ.

A radio program sponsored by the Medical Society of the State of New York should be worthy of civilized human beings. There is no valid reason why a program, unless it is about relativity or the conjugation of Greek verbs, cannot be made entertaining enough to attract a large group of intelligent people. We hope and affirm that such minorities have not as yet lost all privileges and rights. Yet to prepare such programs necessitates much study and technical skill.

Radio is a new modality in the hands of physicians. It must be used with as much skill and technical knowledge as the x-ray or diathermy. If it is so used, much good should result for everyone.

A Notable Feat

The short paper by Jordan¹ and the editorial comment² in the same issue of *Lancet* demonstrate clearly what persistent and painstaking effort will accomplish in eliminating tuberculosis. The report covers a period of ten years, at the end of which time the percentage of positive reactors to 1:1,000 Koch's OT had fallen from 14.1 to 6.75 in a total of 10,907 children examined!

Jordan attributes this drop in the number of reactors to his rigid adherence to the following program: Educational talks and demonstrations to children, parents, and civic bodies; roentgen examination of all reactors; investigation of all suspects and a scrutiny of any possible contacts; follow-up of all reactors with x-ray studies; separation of known cases of pulmonary tuberculosis from contact with children and young adults; and, finally, "stressing the importance of the cattle testing

program, and seeing that it is religiously followed through."

Medicine owes a great deal to the laboratory animal. But "the veterinarians of the United States have set the finest example of tuberculosis control of all time. By following their example, modifying the program as necessary for human beings, Dr. Jordan has set an example which should be followed by every community in the nation." That under his program the incidence of infection has decreased is vastly more significant than any statistical figures depicting morbidity or mortality. It is significant that during this time fourteen teachers with unsuspected clinical tuberculosis were removed as a source of infection, and the investigation has extended to include all employees who come in contact with children. This work is evidence beyond question that "tuberculosis, in communities where transients are not a problem, can be reduced to a minimum."

FOOT FUNCTION CORRELATED WITH ANATOMIC, CLINICAL, AND LABORATORY DATA

R PLATO SCHWARTZ, M D , and ARTHUR L HEATH, B S , Rochester, New York

PARTICULAR ideas regarding foot function have been in use for many years and have become established through repeated examination of the feet in repose. For these reasons foot function is described in terms of characteristic motions and of the names of muscles that activate the respective joints while the foot is at rest. Such information applies specifically to motions of the non-weight-bearing foot on the leg.

But clinical problems in relation to weight bearing do not develop in association with feet in repose. These difficulties are experienced by both children and adults while standing and walking. The high incidence of pronation in feet of persons of all ages makes the characteristics of this abnormality common to most of the clinical problems presented for treatment.

For these reasons clinical observations and laboratory investigations have been directed to the determination of the behavior of the foot with and without the related muscular contractions while walking. The application of this approach requires that we should emphasize the functional characteristics of the skeletal structures of the foot.

These osteoarticular structures develop from cartilage during the period of growth. They are subjected to the stress and strain while supporting body weight during the years of development from cartilage into bone. This influence of function on ultimate form and structure is of primary importance. Malfunctions of the foot during childhood are ultimately combined with the functional limitations provoked by shoes in later decades.

The primary cause of clinical problems in and related to the feet is present throughout life. It is directly associated with the developmental characteristics of the skeletal structures and the medial displacement of the tibia on the os calcis. These factors express their initial influence when the child begins to stand. The structure of the foot and its relationship to the leg direct the body weight

onto the medial aspect of the feet which invariably pronate when children begin to walk. At this time the cartilaginous skeleton of the foot is most susceptible to the reactions defined by Wolff's law "Every change in the form and function of bones, or in their function alone, is followed by certain definite changes in their internal architecture, and equally definite changes in their external conformation, in accordance with mathematical laws."

These cartilages are therefore subjected to influences that cause the proximal surface of the os calcis to rotate inward under pressure from body weight. For this reason the external shape and internal architecture of the bones of the foot are predetermined to express the characteristics of pronation in adult life.

There is no better explanation for the prevailing incidence of pronation in both children and adults. While regarding the influence of these factors on the growing architecture of the foot as a cause for clinical problems, we can also emphasize a fundamental reason why some feet do not pronate.

These are exceptional instances. They likewise require analysis of the characteristics of the os calcis, cuboid, astragalus and their relationship to the tibia. We find that these relationships combine to prevent outward rotation of the heel when the feet support body weight. The axis of weight bearing of the os calcis remains parallel to that of the tibia. With the os calcis in this position, lateral motion essential for pronation is prevented by the interlocking mechanism between the os calcis and the cuboid.

This concept of the factors that promote and prevent pronation may easily be demonstrated on any child or adult. For example, if the examiner will rotate the heel inward, the forefoot cannot be passively rotated into the valgus position. If the heel is then held in external rotation, the forefoot will easily take the valgus position by passive manipulation (Fig 1). This observation has repeatedly been made during the past six years with but one exception to the rule. When an operation was performed on this patient, it was found that the characteristic interlocking relationship of the calcaneocuboid joint was

They Can't Wait Much Longer

Stricken Civilians in England and Greece Need Your Help Today

The Medical and Surgical Supply Committee of America desires to send 1,000 emergency operating sets in khaki canvas rolls and 1,000 fitted first-aid metal cases. These units have been approved, both as to contents and containers, by the surgeons and physicians of this committee. Bombed hospitals, emergency first-aid posts, air-raid shelters, and recently opened auxiliary provincial hospitals are in dire need of instruments to replace losses made almost nightly!

This is a frank appeal to you to come to the assistance of the stricken civilian population of Great Britain and her Allies. If you can interest anyone or any group of people (clubs, factories, commercial organizations, service groups) in your vicinity in the purchase of one or more of these sets, please let us know. Each set will bear a plate with the donor's name, if desired. The price, delivered in England, insurance and shipment included, is \$200 for the Emergency Operating Set and \$70 for the First-Aid Fitted Case.

*Please make checks payable to Arthur Kunzinger,
Treasurer, Medical and Surgical Supply Committee of
America, 420 Lexington Avenue, New York City*

In the first instance a young man had feet which revealed perfect balance before all of the intrinsic and extrinsic muscles of the right foot were paralyzed by complete section of the right sciatic nerve. Although he walked unaided by any form of support for three and one-half years the conformation of the foot remained perfectly normal. We must recognize that the maintenance of alignment between the foot and the leg remained unchanged with use in stance and locomotion, although there was a total absence of muscle function in and related to the right foot. Since the muscles could play no part in "supporting the arches and the maintenance of proper balance of the leg on the foot," the fulfillment of this function must have been expressed by the osteoarticular structures and their relationship to the tibia.

In the second instance special training of the patient had produced normally well-developed extremities. The excellence of coordination was indicated by the fact that she was an advanced pupil in ballet dancing. Bilateral pronation prevailed in standing and walking, but it was fully corrected when she stood on her toes. In the latter position there was a reflex contraction of the posterior tibial muscle.

This patient represents a daily clinical experience characterized by one essential difference. During her four years of ballet dancing this 9-year-old girl had acquired a maximum strength of all extrinsic muscles of the foot, including the posterior tibials. Nevertheless, she had the average degree of pronation, without symptoms, for a child of her age.

By virtue of its origin and insertion, the posterior tibial is the most important extrinsic muscle related to pronation at any age. Any normal individual can correct pronation by voluntary contraction of the posterior tibial in the act of standing and walking. Such voluntary effort cannot be long sustained because of fatigue if not discomfort. In contrast with this required voluntary contraction in stance and locomotion, the posterior tibial muscle contracts reflexly in the act of standing on the toes. By virtue of this reflex contraction, the heel rotates from the valgus to the neutral or varus position, and all characteristics of the pre-existing pronation disappear. This was the functional reaction of the posterior tibial under influences of superincumbent weight as observed in the 9-year-old girl. The young man did not pronate in stance or locomotion although

FIG 2 K M, aged 26. Complete loss of all muscle function and sensation below right knee, no pronation.

there was complete paralysis of all muscles below the right knee, pronation was also absent on the normal left extremity.

These 2 cases, therefore, emphasize that the stability of the leg on the foot in stance and locomotion is not entirely determined by the relative strength of the extrinsic muscles. These clinical observations are further explained by simultaneous records of locomotion and function of the extrinsic muscles.

We have recorded the duration and sequence of contraction of the posterior tibial, anterior tibial, extensor hallucis proprius, extensor digitorum communis, peronei, gastrocnemius, and soleus through the Achilles tendon in relation to the duration and sequence of weight bearing on heel, midfoot, and forefoot.

From these records the functional relationships of the muscles have been measured to the tenth of a second. We are particularly concerned with the sequence and duration of contraction of the posterior tibial and peronei.

FIG 1A

FIG 1B

FIG 1A With the heel fixed in the neutral or varus position the forefoot cannot be put in valgus B With the heel in valgus the forefoot readily takes the valgus position.

replaced by plain surfaces on these bones

In this connection we are all aware of the wide variation in the morphologic characteristics of bones in corresponding feet. Wolff's law is written in every one. The gross characteristics that differentiate one bone from another in the human foot have been determined by the function of walking. The variations found in like bones from 50 adult skeletal feet represent the difference in the function of locomotion which was a personal characteristic of the individual.

The principles thus far stated have emphasized the functional characteristics of the skeletal structures of the foot. Primary consideration has been given to their functional importance in favoring or preventing pronation. In relation to these principles we may refer to clinical evidence from daily practice.

On August 26, 1937, K. M., a white man, 22 years old, sought relief from complete loss of sensation and muscle function in the right leg and foot. Eighteen months had elapsed since he had suffered a compound comminuted fracture in the distal third of the right femur. The fracture had healed and he could walk unassisted without apparatus, crutch, or cane. Operation revealed that the sciatic nerve had been completely severed at the time of the accident. Despite the fact that

both intrinsic and extrinsic muscles of the foot had been paralyzed during a full year of weight bearing on the extremity, he had no pronation, nor was there any pronation of the uninvolved left foot. This was also the status of the patient when he was seen on April 10, 1940, over four years after the accident (Fig. 2).

The second patient was a 9-year-old girl who had no complaints. During the past four years she had become proficient as a ballet dancer. Her mother had become concerned about the increasing lateral deviation of the great toes, particularly the left. Examination revealed bilateral pronation, the left foot was worse than the right. This relative degree of pronation was present in relation to both stance and locomotion. When she was asked to stand on her toes, it was noted that the valgus position of the os calcis was fully corrected and that the previously existing pronation likewise had disappeared (Fig. 3).

In the light of the facts presented by these 2 patients we must reconsider the traditional statement that exercises should be used to develop the intrinsic and extrinsic muscles of the foot in order that their maximum efficiency in function might adequately support the arches and maintain the best balance of the leg on the foot while standing and walking.

the act of standing on the toes the reflex or involuntary contraction of this muscle removes all of the pre-existing characteristics of pronation. On the basis of strength the posterior tibial demonstrates its power to serve this function in all normal children and adults. For this reason the prevailing incidence of pronation in all age groups cannot be adequately explained on the basis of weak muscles. Nor can the absence of pronation be accounted for on the basis of strong muscles.

Both the clinical evidence and the simultaneous records of locomotion and extrinsic muscle function lead to only one conclusion. The presence or absence of pronation is primarily dependent upon the maintenance of a parallel between the axis of weight bearing of the os calcis and that of the tibia.

The strength of the posterior tibial is normally adequate for this purpose, but in normal stance this muscle is not called upon to exert its functional efficiency. Under the influence of body weight the os calcis rotates into valgus, the astragalus sinks into position, and the foot presents the characteristics of pronation. The occasional absence of pronation cannot be attributed to exceptional strength or to the sequence and duration of posterior tibial contraction in relation to the peronei muscles. It is more properly accredited to those essential osteoarticular relationships that maintain the parallel axis between the heel and the leg, thereby locking the cuboid and preventing pronation of the foot.

Conclusion

Clinical experience and laboratory investigation require that we reconsider the relationship of pronation to the strength of the extrinsic muscles of the foot.

Clinical evidence presented proves that perfect alignment between foot and leg can be maintained during four years of use following complete paralysis of all intrinsic and extrinsic muscles of the right foot.

The presentation of a second patient proves that unusually well-developed muscles do not prevent pronation in stance and locomotion.

Simultaneous records of muscle function and foot function while walking prove that the reflex contraction of the posterior tibial

FIG. 4. Average sequence and duration of weight bearing on heel, midfoot, and forefoot as related to sequence and duration of contraction of the posterior tibial and peroneal muscles.

is inadequate for prevention of pronation.

Both the presence and absence of pronation are explained on the basis of the functional characteristics of the os calcis, cuboid, and their physical relationship to the astragalus and tibia. A neutral or varus position of the os calcis does not permit pronation of the forefoot.

Muscle exercises are contraindicated for the correction of pronation. Treatment is limited to measures that will maintain a neutral or varus position of the os calcis.

PHYSICIANS NEEDED

A total of 9,100 physicians, of whom 5,300 must be procured during the next few months, will be required for the total strength of the Army of the United States next spring, which will be approximately 1,400,000 men, the surgeon general of the

Army declares in an outline regarding the participation of the Army Medical Department in the 1940-1941 military training program, published in the *Journal of the American Medical Association* for December 7.

Fig 3 G S, aged 9 Four years training in ballet dancing A and B Bilateral pronation C and D Reflex contraction of posterior tibial muscles corrects pronation, heels in varus position

muscles as related to the beginning and duration of weight bearing on the heel (Fig 4)

The heel receives and supports body weight for 0.436 seconds. The posterior tibial muscle contracts simultaneously with placement of the heel on the floor, but its duration of contraction is only 36.1 per cent of the total stance phase of the step, 0.694 seconds, 57.5 per cent of the total time the heel is on the floor. Therefore, it is evident that this short period of reflex function of the *tibialis posterior* does not prevent the foot from pronating while walking.

This too early discontinuance of a positive force that could prevent pronation is accompanied by peroneal contraction which further provokes the characteristics of pronation in each step. The *peronei* begin to contract 0.166 seconds after the heel contacts the floor and continue to contract for 79.8 per cent of the stance phase of the step as against 36.1 per cent previously stated for the *posterior tibial*.

These measurements emphasize the impor-

tance of knowing the relative sequence and duration of muscle function in the act of walking. An understanding of these values immediately introduces a fundamental change in the point of view regarding the cause and prevention of pronation.

It becomes evident that relative muscle strength is important only when opposing muscles are reflexly called upon to contract simultaneously. Herein we are confronted with the necessity of evaluating the relative efficiency of muscle function in terms of relative strength, sequence, and duration of contraction as related to its antagonist.

Evaluation of relative efficiency of muscle function should not be based upon determination of relative strength of muscles while the patient is in repose. The relative sequence and duration of contraction is essential information without which valid conclusions are not possible.

As previously stated, pronation is easily corrected by voluntary contraction of the *posterior tibial* in standing and walking. In

the act of standing on the toes the reflex or involuntary contraction of this muscle removes all of the pre-existing characteristics of pronation. On the basis of strength the posterior tibial demonstrates its power to serve this function in all normal children and adults. For this reason the prevailing incidence of pronation in all age groups cannot be adequately explained on the basis of weak muscles. Nor can the absence of pronation be accounted for on the basis of strong muscles.

Both the clinical evidence and the simultaneous records of locomotion and extrinsic muscle function lead to only one conclusion. The presence or absence of pronation is primarily dependent upon the maintenance of a parallel between the axis of weight bearing of the os calcis and that of the tibia.

The strength of the posterior tibial is normally adequate for this purpose, but in normal stance this muscle is not called upon to exert its functional efficiency. Under the influence of body weight the os calcis rotates into valgus, the astragalus sinks into position, and the foot presents the characteristics of pronation. The occasional absence of pronation cannot be attributed to exceptional strength or to the sequence and duration of posterior tibial contraction in relation to the peronei muscles. It is more properly accredited to those essential osteoarticular relationships that maintain the parallel axis between the heel and the leg, thereby locking the cuboid and preventing pronation of the foot.

Conclusion

Clinical experience and laboratory investigation require that we reconsider the relationship of pronation to the strength of the extrinsic muscles of the foot.

Clinical evidence presented proves that perfect alignment between foot and leg can be maintained during four years of use following complete paralysis of all intrinsic and extrinsic muscles of the right foot.

The presentation of a second patient proves that unusually well-developed muscles do not prevent pronation in stance and locomotion.

Simultaneous records of muscle function and foot function while walking prove that the reflex contraction of the posterior tibial

FIG 4 Average sequence and duration of weight bearing on heel, midfoot, and forefoot as related to sequence and duration of contraction of the posterior tibial and peroneal muscles

is inadequate for prevention of pronation.

Both the presence and absence of pronation are explained on the basis of the functional characteristics of the os calcis, cuboid, and their physical relationship to the astragalus and tibia. A neutral or varus position of the os calcis does not permit pronation of the forefoot.

Muscle exercises are contraindicated for the correction of pronation. Treatment is limited to measures that will maintain a neutral or varus position of the os calcis.

IMMUNE GLOBULIN (HUMAN) IN THE MODIFICATION AND PREVENTION OF MEASLES

HAROLD W LYALL, Ph D , and PHILIP P MURDICK, Ph D , Albany, New York

IN VIEW of the higher mortality from measles in young children, it is generally accepted that its modification or prevention in those under 4 years of age is a desirable public health measure. The value under similar conditions of the various preventive agents that have been recommended—convalescent serum, parent's whole blood, and placental extract—appear approximately the same. Convalescent serum, because of the lack of suitable donors, is, however, difficult to obtain in sufficient quantity. Adult blood because of the greater volume that must be administered is not favored by physicians. Therefore, on the basis of reports by McKhann^{1,2} of the satisfactory results from the use of an extract of human placentas and because of the availability of this material, the preparation and distribution of globulin solution (human) under certain restrictions was begun in 1935 by this division*. Since that time and particularly during 1938 and 1939 when the incidence of measles was high a considerable amount has been used by physicians. The reports received record the results obtained in private practice and an analysis of these data seemed of interest. For purposes of comparison, reports on the use of the globulin solution in children in institutions have also been included.

The proper dosage of globulin solution is related to a number of factors such as the age and physical condition of the child, the intimacy of exposure, and the interval between exposure and treatment. Since there is at present no satisfactory laboratory test for evaluating the potency of the product, its efficacy must be judged by the results of clinical trial. The method of preparation³ is essentially that described by McKhann. To promote uniformity, each lot is prepared from the pooled extracts of at least thirty placentas, and the total solids content of the concentrated globulin solution is adjusted to between 5 and 7 per cent. An injection of from 2.5 to 5 ml. is at present recommended.

Table 1 gives an analysis by age groups of

the results obtained in 457 children treated in private practice. As would be expected, the greatest degree of protection is found in children under 6 months of age. Special interest, however, centers in the infants of this age group who developed measles notwithstanding preventive treatment, since this has a bearing upon the question of maternal transmission of immunity. The previous history relating to measles of the mothers of 16 of the infants from 10 days to 5 months old was secured. Of the 3 in the series who developed measles—2 infants 3 months old and one 2 months old—the mothers of 2 gave a history of measles and that of the third did not. All but 2 of the mothers of the remaining 13 infants who did not develop measles were recorded as having had the disease. The fact that the incidence of measles was highest in the group between 1 and 3 years of age is of interest, but this could not be correlated with differences in dosage, degree of exposure, or interval between exposure and treatment. It suggests that maternally transmitted immunity has disappeared at this age and that whatever natural immunity may possibly be acquired has not developed up to this time. In spite of the greater incidence of measles in this group, failure to modify or prevent the disease occurred in only 7.1 per cent of the cases. This figure compares favorably with the results in the other groups and also with those reported by McGavran⁴ for children treated in private practice.

Six severe cases of measles were reported. Three occurred in children who were healthy at the time of exposure and had no subsequent complications. One recovering from a mastoid operation had a cervical adenitis with a return of the mastoid infection. Another developed measles following bronchopneumonia complicated by pyelonephritis. The sixth child, who had bronchitis, developed otitis media following measles. All recovered.

The results of preventive treatment in 201 children in institutions are analyzed similarly in Table 2. That the intimacy of contact among them is, on the whole, greater than that in the groups given in Table 1, which include both intimate and casual contacts, is indicated by the relatively less complete pro-

From the Division of Laboratories and Research, New York State Department of Health.

tection afforded. There was also a greater proportion of moderate and severe cases, although there were no fatalities. Both groups were alike in that the greatest incidence of measles occurred between 1 and 3 years of age. No data for infants under 6 months are, however, available for this group.

Further discussion is limited to the children treated in private practice. The effect of the interval between the exposure to measles and the injection of the globulin solution is given in Table 3. Before the third day a larger percentage is protected against the disease, but thereafter there is no decided trend.

When the children are grouped according to the degree of exposure—definite, probable, or possible—only 2 in the "probable" group and none in the "possible" group developed the disease. If the 86 children in these two groups who did not contract measles are deducted from the total for all age groups in Table 1, there still remain over 90 per cent who either did not develop measles or had the disease in a mild form.

The dosage of globulin solution injected varied from 1 to over 6 ml. Since the reports did not indicate whether the physician's aim was to modify or prevent the disease, information as to the proper dosage for either purpose

is inadequate. However, a greater degree of protection was afforded by 5 ml. than by the lesser doses.

Mild reactions consisting chiefly of local soreness and swelling were reported in 25.4 per cent of the children, and an additional 3.9 per cent developed general reactions with fever or malaise. One child of this latter group also had hives five days following the injection. However, none of the reactions was considered alarming.

Summary and Conclusions

1 In a series of 457 children who were reported as having had close or casual exposure to measles and who were treated with globulin solution in private practice, 93.5 per cent either had the disease in a mild form or were protected against it, in comparison with 77.6 per cent of 201 children in institutions.

2 The results indicate that children between 1 and 3 years are apparently more susceptible to measles than those in other age groups.

3 The greatest protection against measles in the children treated in private practice was obtained in those injected before the third day following exposure.

4 One dose of at least 5 ml of the product distributed appeared necessary if prevention of the disease was desired. However, the many variable factors make it impossible to recommend a definite optimum dose.

5 No serious or alarming reactions followed injections in this series.

DISCOVERY OF NEW VACCINE AGAINST THE FLU

The recent discovery of a new vaccine against influenza is hailed by the *Journal of the American Medical Association* for January 11 as one of the most promising practical leads in research of recent decades because it opens up new fields of thought and investigation regarding immunity.

"The new vaccine against influenza recently described by Drs F L Horsfall, Jr, and E H Lennette of the Rockefeller Foundation challenges conventional immunologic theory," the *Journal* says. "The vaccine seems to have been a purely accidental discovery. About a year ago numerous normal ferrets were inoculated intranasally in the Rockefeller Foundation laboratory with the 1939 strain of human influenza virus. During the course of the resulting influenza, four of these animals developed a concurrent infection with ferret distemper. In order to prevent the spread of this epizootic to the stock animals, a formalized vaccine was prepared from the lungs and spleens of these ferrets and injected subcutaneously into each of the 157 normal animals of the ferret colony. Similar vaccines had been found effective in preventing the spread of ferret distemper on previous occasions.

"Two days after inoculation with this pre-

sumptive distemper vaccine, groups of the vaccinated ferrets were inoculated intranasally with massive doses of three antigenically distinct strains of human influenza virus. To the great surprise of the New York investigators, none of these animals developed experimental influenza. Injection of the presumptive distemper vaccine had apparently resulted in immunity effective against at least three antigenically different strains of influenza virus. This is a broader and more effective immunity than results from actual infection with the influenza virus.

"After numerous failures it was found possible to reproduce this mixed vaccine by inoculating ferrets simultaneously with mixtures of human influenza virus and canine distemper virus. The formalized vaccines thus produced not only protected ferrets against canine distemper but afforded almost absolute protection against massive intranasal doses of all strains of human influenza virus thus far tested. These vaccines have been tested on human volunteers. In all instances they produced a definite increase in mixed virucidal antibodies, apparently active against the available strains of human influenza virus."

COURSES ON GENERAL MEDICINE

Dr William S Ladd, Dean of the Cornell University College of Medicine, has arranged a course on general medicine for the Tompkins County Medical Society. The lectures will be given at Ithaca at 8:15 P.M. and are as follows:

March 3, "Endocrine Problems in Adolescence," by Dr Harry H Gordon, March 19, "The Significance of Laboratory Tests and Methods in the Practice of Medicine," by Dr Ralph G Stillman, April 7, "Newer Chemotherapeutic Methods," by Dr Norman Plummer, April 15, "The Relation of Vitamins to Disease," by Dr Norman Jolliffe, May 5, "Abdominal Pain," by Dr Edward M Livingston.

Dr Albert F R. Andresen, of Brooklyn, has arranged a course of lectures on general medicine for the Columbia County Medical Society. These lectures will be held at the Hudson City Hospital, Hudson, New York, at 9:15 P.M. March 27, "Dietary Therapy in Gastrointestinal Disease," by Dr Andresen, on April 10 "The Diabetic Patient and the General Practitioner," by Dr Milton B Handelsman, on April 24, "Some Problems in Cardiac Diagnosis," by Dr J Hamilton Crawford, on May 8, "Practical Considerations of Blood Dyscrasias," by Dr Eugene R. Marzullo, on May 22, "Recent Advances in Therapeutics," Dr George H Roberts, all the doctors are from Brooklyn.

EXAMINATIONS—AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY

The general oral and pathologic examinations (Part II) for all candidates (Groups A and B) will be conducted at Cleveland, Ohio, by the entire Board from Wednesday, May 28, to Monday, June 2, 1941, inclusive, prior to the opening of the annual meeting of the American Medical Association in Cleveland, Ohio.

Application for admission to Group A, Part II, examinations must be on file in the Secretary's Office not later than March 1, 1941.

Candidates for re-examination in Part II must make written application to the Secretary's Office before April 15, 1941.

The Board requests that all prospective candidates who plan to submit applications in the near future request and use the new application form which has this year been inaugurated by the Board. Address Dr Paul Titus, Secretary, 1015 Highland Building, Pittsburgh (6), Pennsylvania.

THE IMPORTANCE OF CHRONIC SINUSITIS IN THE TREATMENT OF BRONCHIAL ASTHMA

R. CLARK GROVE, M D, New York City

HERCK,¹ of Freiberg, in 1844 first recognized the importance of nasal pathology in asthma. However, it was not until 1872 that the effect of sinus surgery upon asthma was demonstrated when Voltolini² reported 11 cases of asthma relieved by polypectomy. Since that time the frequency and importance of sinusitis in asthmatic conditions has been argued pro and con and the treatment has varied from conservative and radical surgery to no surgery at all. I³ believe sinusitis is an important factor in asthma, and to justify this belief I will discuss the incidence of sinus infections in asthmatic patients, the type of pathology, the bacteriology of the sinus membranes, and the effect of sinus surgery.

Dundas-Grant⁴ stated that 63 per cent of 107 cases of asthma had sinusitis. Gottlieb⁵ found only 26 per cent of 117 cases. Kern and Schenck⁶ in 1933 stated that in 400 cases of asthma 70 per cent had clinical sinusitis and 87.5 per cent showed x-ray evidence. Chobot,⁷ studying children up to 15 years of age, found x-ray evidence of sinus disease in 67 per cent in 1933^{7a} and 41 per cent in 1930.^{7b} Kelley⁸ recently reported that 89 per cent of 100 cases of asthma had rhinologic and x-ray evidence of sinusitis. Twenty-six per cent of the 89 cases had nasal polyps.

In a study published in 1932 and based on 688 cases of asthma, Cooke⁹ found sinus disease to be the cause in 39 per cent of 257 cases in whom asthma began between 10 and 30 years of age, 65 per cent of 171 cases between 30 and 50 years, and 83 per cent of 42 cases after 50 years. Dental, tonsillar, pharyngeal, and primary pulmonary infections may also be causes of infective asthma. Infection was the sole cause of asthma in 34 per cent of the 688 cases, and combined with other sensitizations such as danders, pollens, or food it was an additional cause in 15 per cent, making a total of 49 per cent of all asthma caused by infections of all types. If we exclude the cases in the first decade, since the tonsils and lymphoid tissues of the nasopharynx and pharynx are more important at that time, we find that 53 per cent of the remaining 470 cases was

caused by infection with 8 per cent being due to primary pulmonary infections, leaving 45 per cent with sinusitis as the only cause.

It is interesting to note in passing that Bullen¹⁰ in 1933 reviewed 93,000 admissions to three general hospitals in Rochester and found that 1.2 per cent warranted a diagnosis of disease of the paranasal sinuses. It was most frequent in the latter half of the first decade of life and between the ages of 30 and 50 or 55 years. He studied 400 of these cases of sinusitis and found that about one-fourth had some form of chronic nontuberculous pulmonary disease. 12.25 per cent of them had asthma, while 8.75 per cent actually had asthma begin at the same time as the sinusitis or later. Bullen was not very enthusiastic about sinusitis being a cause of asthma, but when we consider that the allergic proportion of our population is now approximately 10 per cent we know why his percentage of asthma was so low. I believe that sinusitis as a cause of asthma must occur in a person with an allergic constitutional tendency. Cooke⁹ in the previously quoted group of 688 cases found that there was a positive antecedent history of allergy in 45 per cent of the entire infective group and 52 per cent of the atopic ones. Sixty-six per cent of 195 cases of asthma gave an antecedent history of asthma. Clarke, Donnelly, and Coca,¹¹ however, quote 80 per cent.

The pathology of the nasal and sinus membranes in asthmatic patients is well recognized. In our experience almost 100 per cent of the pathology is of the hyperplastic type as contrasted with the suppurative. There may be exacerbations of the infection, and pus is present in the washings and the neutrophils predominate in the membranes at the time, but this is only temporary. The true hyperplastic membrane is much thickened, often infolding and polypoid, with desquamation of the cilia, a thickened hyalinized basement membrane, and in the tunica propria, marked edema, glandular hyperplasia, proliferation of the connective tissue, and eosinophilic, round, and plasma cell infiltration. In the chronic cases neutrophils are not frequent. The bronchial and ocular membranes have shown the same general characteristics on pathologic examination. Polyposis occurs in from 30 to

35 per cent of the cases with pathology. We have also had these membranes cultured and found that 87 per cent showed positive culture of one or more organisms. Only 1 of 29 antral membranes examined were negative, while 16 of 51 ethmoidal and sphenoidal membranes were negative. This is easily explained when we realize that most of these specimens were mucous or cystic polyps, the contents of which are usually sterile, the infection being in the cyst wall or underlying membrane. Thirty-four of the positive cultures yielded a single organism. This seems important from the standpoint of the value of the organism as an etiologic agent in the disease. When we compared the organisms obtained from 80 sinus membranes with those grown from previous washings of the antrums, we were surprised to find that in 43.7 per cent the membrane cultures were different from those recovered preoperatively. It is our belief that a clear return from irrigation of an antrum even with a negative culture does not indicate a normal or noninfected sinus.

The tissues removed from the sinuses were stained and in over 85 per cent bacteria were demonstrated definitely while the remaining 15 per cent was too questionable to be considered positive. The percentages obtained from a recent study of 108 membrane cultures were as follows: *Staphylococcus aureus*, 57 per cent, *Streptococcus viridans*, 43 per cent, hemolytic streptococcus, 25 per cent, *Micrococcus catarrhalis*, 3 per cent, nonhemolytic streptococcus, 3 per cent, *Bacillus proteus*, 2 per cent, pneumococcus, 39 per cent, diphtheroid bacillus, 2 per cent, no growth, 9 per cent. Kistner¹² in 1931 studied 400 sinus membranes of the nonpurulent type and found streptococci present culturally in 94.5 per cent of the cases. Rosenow of the Mayo Clinic checked some of his specimens microscopically and agreed that the membranes were infected. Hansel,¹³ Piness and Miller,¹⁴ Ashley and Frick,¹⁵ and Balmer¹⁶ believe that

organisms in the membrane are secondary invaders, but from our own studies we cannot accept this explanation.

The question now arises: How are we going to diagnose sinusitis in allergic patients? The answer is by careful history-taking, clinical, and x-ray examinations. The history of frequent colds, stuffiness, nasal discharge, anteriorly or posteriorly, sneezing, and headaches is important, but frequently all of these symptoms are absent. The nasal examination must include anterior rhinoscopy followed by nasopharyngoscopic examination. This is important, as, otherwise, discharge from the antrum, posterior ethmoids and sphenoids, and small polyps posteriorly may be overlooked. Transillumination should be done, but if this is clear the examination is not complete. Good roentgenograms are important, especially for diagnosing polyps and cysts of the antrum. Recently we have been injecting the antrums with an opaque medium and re-x-raying these doubtful cases. If necessary, lavage of the antrum should be done, and the discharge should be centrifuged and examined microscopically for eosinophilic cells. We usually make cultures of the return flow also.

Once the diagnosis of sinusitis is made, the form of treatment must be determined. If polyps are present in the ethmoids or sphenoids, they should be removed if the asthmatic and general condition justifies this procedure. By removal of polyps we do not mean a simple polypectomy but an exenteration of the ethmoids or sphenoids. Polyps, cysts, and extensive thickening of the membrane of the antrums require a Caldwell-Luc operation. We have not been satisfied with the result obtained by doing simple antrotomies or window resections. In conjunction with these operations, submucous resections and turbinectomies were done for the effect upon the sinus condition and not as a direct benefit to the asthmatic condition. If the sinus infection is of a low grade or mild form, antrum irrigations or occasionally an antrotomy, removal of adenoids and tonsils and infected teeth, and the use of vaccine, both autogenous and stock, will normally suffice for treatment. Regardless of the degree of sinusitis, complete allergic testing and treatment is necessary. A large number of cases of recurrent polyposis may be cured if the dust or other inhalant allergens are used when indicated, both before and after the operation. Blood examinations including Wassermann, kidney and chest examinations including x-rays and sputum for tuberculosis,

TABLE 2—AN ANALYSIS OF RESULTS OF SINUS SURGERY IN 200 CASES OF ASTHMA BASED ON COMPLETENESS OF REMOVAL OF ALL SINUS PATHOLOGY

molds, and spirochetes are usually indicated. Recently the question of vitamin deficiency has been emphasized, and a good many of these patients improve with the addition of these concentrates to their medication. At present we are interested in the vitamin A deficiency in our chronic hyperplastic sinus infections.

In discussing the effects of sinus surgery upon asthma, I will not go into the details of the frequency of the various sinuses involved or the surgical technic but will simply state that our operative group includes 192 ethmoidectomies, 94 sphenoidectomies, 113 radical antrums (Caldwell-Luc type), 66 antrotomies (window resections), and 6 enlargements of the frontonasal duct.

Results

The results of our sinus surgery in 200 cases of asthma are shown in the three tables. Table 1 analyzes the entire group according to the postoperative duration of time. We have not included the first six months because we believe the effects of the anesthetic and the reaction to handling infected tissues may be factors in the immediate improvement or the exacerbation of asthmatic symptoms. The improved cases represent 69.5 per cent of the total cases. It is also seen that as the duration of the postoperative period increases the ratio of the improved group to the unimproved increases. I believe that this is explained by the fact that there are secondary foci in the cervical and bronchial lymphatic glands and the bronchial mucosa, and these secondary foci heal slowly after the removal of the primary focus. The patients who did well from the immediate postoperative period and continued so for the six years may not have had such secondary involvement, and, on the other hand, the ones who never did well may lack the capacity to heal the secondarily involved infections.

TABLE 3—FURTHER ANALYSIS OF RESULTS OF SINUS SURGERY IN 200 CASES OF ASTHMA, DIVIDED ACCORDING TO ETIOLOGY OF ASTHMA AND TYPE OF OPERATION

	+	++	+++

		87 7%	7
Incomplete surgery (41 cases)	14	20	65 9%
Window Resections (27 cases) (Antrotomies)	16	6	5
		40%	39
Radical Antra (94 cases)	23	32	75 5%
Radical Antrum Following Window Resection (19 cases)	4	8	79%

* The symbol + indicates slight or no improvement in asthma ++, definitely improved, +++ no asthma or a rare attack

Table 2 divides the 200 patients into those who have all the indicated sinus surgery completed and those who for one reason or another were still incomplete. The complete group includes the radical antrums and ethmoidal and sphenoidal operations, while the incomplete group includes the simple removal of polyps and middle turbinates and antrotomies. Also, if ethmoidal and antral operations are indicated and only one is done or if both sides are involved and only one is operated on, this case is classified as incompletely treated surgically. The difference in the effect upon the asthma is quite striking. The complete group showed an 85 per cent improvement, while the incomplete group showed only 54 per cent.

In Table 3 we have classified the 200 cases according to the type of asthma, that is, purely infective and infective associated with skin-sensitizations, the so-called combined type. The results of complete and incomplete sinus surgery in these two types is then analyzed. The combined type showed a better result. This group was also treated with injections of the indicated allergens. Both types were treated in the majority of cases with autogenous vaccines made from the sinus membranes removed at operation.

Table 3 also includes a comparison of the results obtained after performing an antrotomy or a radical antrum operation and 9 cases who had a radical operation performed secondary to a previous antrotomy. The radical antrum cases showed almost twice as great an improvement.

Summary

Disease of the paranasal sinuses is an important focus of infection in asthma. I believe that infective asthma is the result of a sensitization to bacteria or to their products in an individual with an allergic constitution.

In order to obtain accurate information as to the effect of sinus surgery upon patients with asthma it is necessary (1) to study the etiologic factors, that is, whether solely infection or infection associated with demonstrable skin-sensitizations, and (2) to analyze the type of sinus surgery as to whether it is complete or incomplete.

Two hundred cases of asthma with disease of the paranasal sinuses treated surgically were followed postoperatively for from six months to six years, with 69.5 per cent showing definite improvement. Of those who received complete surgical treatment 85 per cent were improved as contrasted with 54 per cent in the group who had only partial surgery. Immediate improvements should not be expected, and our results show that with increasing postoperative period of time the best results are obtained. We believe that this is due to the gradual elimination of infection in the cervical and bronchial lymphatic glands and the bronchial mucosa.

Surgical procedures on the paranasal sinuses cannot be expected to produce improvement of the asthmatic condition if extranasal infections such as those due to molds, spirochetes, and tubercle bacilli, as well as any associated allergies of the "skin-sensitive" type, are not taken into consideration. Autogenous vaccines are also important in the treatment of all of our cases.

FAMILY DOCTOR REBORN AS TRIPLETS

The family physician of a generation ago finds his counterpart in modern medicine in three men, Dr. R. S. Cunningham, dean of Albany Medical College, told the Visiting Nurse Association in Albany the other day.

"One hundred years ago the total knowledge in medicine was within the compass of a single mind," he said. "All the technical expression of medical knowledge could be acquired by a single individual and a practicing physician could serve his community with no other help than he derived from his friends."

"But times have changed. The tremendous increase in knowledge and the development of many special technical procedures have made it necessary for medicine to find new methods of expression, and this has resulted in the general practitioner being, like ancient Gaul, divided into three parts."

Dr. Cunningham told the nurses those three divisions that make up the relationship of the patient to the physician are diagnosis, treatment, and a comprehensive sympathetic understanding.

"Therefore, today we offer you in place of the family physician, three men: one trained to recognize disease, one trained in specialized therapy, and one trained in the problems of social adjustment of the individual. We still have the family physician, altered in number but not in service. Once he was one, now he is three."

HOW TO STAGNATE IN MEDICINE

There are several rules which must be kept in mind, if we wish to deteriorate in medical skill and knowledge, says *Clinical Medicine and Surgery*.

The first rule: File your patient's records away and forget all about them. Never go over them after the day's work is done and try to pick out errors of omission or commission, never try to follow up patients to learn whether your diagnosis was correct and your treatment helped the patient. Best of all, keep only a few scribbled lines about each case, preferably without making any attempt at a diagnosis.

The second rule: Read medical books and magazines with an eye only for the "practical"—that which can be used at once. Skip over the physiology, pathology, and differential diagnosis so that you can concentrate on treatment. Read the summaries at the end of articles, only a sucker will dig through the article itself.

The third rule: Never take a chance on confirming your diagnosis by consultation with a specialist (unless, of course, an unreasonable patient insists on it and you can't snub the bouncer) or by necropsy. Thus you can cheerfully go ahead making the same mistakes over and over. Most people don't know the difference anyway.

By following these basic precepts and by avoiding postgraduate courses and medical meetings, you may be assured of a comparatively rapid, and certainly unlaborious, decadence.

THE BEHAVIOR OF TUMORS IN TISSUE CULTURE AT TWENTY-FOUR HOURS

EDWIN J. GRACE, M.D., F.A.C.S., Brooklyn

IN REVIEWING the data that has accumulated since the first reports on the growth of human tumors in tissue culture by Loeb, Burrows, and later Carrell nearly thirty years ago, one is impressed by the meager help that has accrued to the clinician from these investigations. Numerous studies have been reported, all attempting to make available a permanent supply of tumor tissue for experimental study and comparison. In spite of this commendable effort, little has been done to use growth in tissue cultures as a means to explain the wide difference seen in the behavior of cancer clinically.

Early in our investigations we noted that various tumors exhibited differences of behavior within twenty-four hours after culturing. An effort was therefore made to ascertain whether or not such differences might be related to the grade of the malignancy of the tumor as seen clinically. If such were the case, a study of the phenomena underlying these differences might contribute to our knowledge of the biology of tumor cells, and the different types of behavior in tissue culture might have diagnostic value in the case of tumors difficult to classify by the usual methods.

In most cases the operation from which these specimens were taken occurred about 9:00 A.M., and the cultures were made during the early afternoon of the same day.*

The medium used was as follows: one volume of chick embryo extract, one volume of a mixture of three parts of human blood serum (from any source), and one part of chicken blood plasma.

Twelve to fifteen explants were made from each tumor. In the majority of cases most of the explants exhibited a similar type of behavior (see Figs. 1, 2, 3a and b, and 4).

Thirty-seven tumors are reported. Fifteen others were cultured, but reports on them are excluded because of contamination or other adverse conditions. Although this number is larger than that involved in other studies, nevertheless conclusions must be regarded as tentative, since the types of tumors studied are

diverse and the number in any one grade is small.

The differences in behavior of the tumors exhibited under tissue culture conditions fall into three categories: (1) the degree to which they liquefy the medium, (2) the presence of wandering cells which are more or less rounded but have an irregular shape (probably leukocytes and macrophages), and (3) the presence of elongated cells which are fibroblasts.

The fibroblast-like cells that are present in the most active tumors make their appearance within a brief period that is not typical of ordinary fibroblasts of normal adult mammalian tissue, the latter usually have a latent period of at least twenty-four hours before they first make their appearance and then are just beginning their growth. In the tumors, however, these cells when present are abundant and have grown out from the explant. All these cells are probably not tumor cells but represent the defensive cellular mechanism found in the cancer bed.

The variations in behavior have been arbitrarily grouped into four classes as follows: grade I—no liquefaction of the medium and no visible cell activity (benign tumor), grade II—slight liquefaction and the presence of a few wandering cells (low grade or grade I), grade III—much liquefaction and the presence of many wandering cells (medium—grades II and III), and grade IV—much liquefaction and the presence of many wandering cells (as in grade III) and, in addition, fibroblasts (high—grade IV).

The major result is as follows: human tumors, after twenty-four-hour period under tissue culture conditions, if benign, show no activity with one exception, if malignant, they exhibit various degrees of activity, again with an exception. In general, the degree of activity is probably related to the degree of malignancy. This result is apparent from a study of the data of Fig. 5.

The two exceptions noted should not, however, be minimized. (1) Fibroid tumors of the uterus are known to be benign except for about 2 per cent of cases, yet of the eight cultured in this study, four exhibited no activity as is expected, but four others showed slight activity. (2) Metastatic tumors of the axillary gland (breast carcinomas) would be expected

* Read at the Annual Meeting of the Medical Society of the State of New York, New York City, May 8, 1940.
From the Grace Clinic, Brooklyn.

* The culturing was done in the biologic laboratories of Chambers by Miss Gladys Cameron at Washington Square College, New York University.

FIG 1

FIG 1 Picture of an explant of a benign tumor at the end of twenty-four hours in tissue culture. There is no evidence of growth.

FIG 2

FIG 2 Picture of an explant from a low-grade malignant tumor at the end of twenty-four hours showing liquefaction of medium about the explant.

to show extensive activity, yet three such tumors showed none at all.

In active surgical practice it is absolutely apparent that carcinoma behaves in humans in many different ways, but on analysis the clinical picture bears a definite relation to the cellular makeup of the tumor, the reaction of the tissue in the cancer bed, and the anatomic position of the growth. The most vital of these is, of course, the cellular makeup, and it represents the biologic unit on which the whole cancer problem exists. Clinically, cancer is nothing more or less than the composite picture of this atypical cell behavior.

The cells in all neoplasms show a tendency to maintain a normal, adult, cell architecture (differentiated) or to show active cell growth not imitating the parent cell histology (undifferentiated), and within the confines of this cellular phenomena and the anatomic area involved rests the entire clinical picture of cancer.

In 1929, following the technic of Broders, I confirmed in a series of carcinoma of the breast the clinical importance of grading tumors and further demonstrated that the higher the grade of the tumor, the greater the tendency to metastasize, and the more remote the metastasis from the primary tumor, the higher the grade of the tumor, and, conversely, the lower the grade of the tumor, the less tendency to metastasize. These observa-

tions compelled me to try further for confirmatory evidence, and these studies resulted.

With these clinical facts in mind, it was the purpose of the study reported here to demonstrate from the primary tumor what fundamental biologic difference might be involved, to determine whether the cells that constitute malignant tumor could be grown in tissue culture, and whether the rate of growth in tissue culture would parallel the grade of malignancy.

It was apparent at the outset that the cellular activity seen in tissue culture was not the cellular makeup of the original tumor, and a review of many of the reports in the literature leads one to question whether some cellular elements from the cancer bed were not grown, rather than the cancer cells as we recognize them at present.

In discussing the cellular element in cancer from a clinical point of view, two interesting facts stand out—namely, that the more differentiated the cell, the less tendency there is for metastasis, and, conversely, the more undifferentiated the cells, the greater the tendency to metastasis. Clinically, this fact is significant as in cancer of the colon, the well-differentiated adenocarcinoma will kill by obstruction unless relieved surgically, while the high-grade, undifferentiated adenocarcinoma may not obstruct but will kill by metastasis. These fundamentals in biopathology of the

FIG 3a

FIG 3b

Fig 3a Picture of an explant from a high-grade tumor showing marked evidence of growth in tissue culture at the end of twenty-four hours. Growing cells are probably fibroblasts.

Fig 3b This picture shows a higher magnification of Fig 3a cells growing from periphery of explant in a high-grade malignant tumor in tissue culture at the end of twenty-four hours.

so-called cancer cells are not sufficiently appreciated by all clinicians. I feel that if all surgeons would give more consideration to the biopathology of cancer they would, when approaching the problem as technicians, be compelled to see the appalling limitations of their efforts.

It is generally true that although both types of cells may metastasize it is the undifferentiated cells that are seen most often in metastatic nodules.

In the reports in the literature on growing cancer there seems to be considerable discrepancy between the type of cellular growth seen proliferating from the cancer in tissue culture in twenty-four hours and not dissected from its cellular bed and the cells seen in the cancer specimen stained for routine diagnosis.

It is extremely difficult to define the cancer cell, but, if we use the criteria described by MacCarty as a cell "in which there is a marked alteration in the nuclear-neucleolar ratio which is a phenomena not seen in any normal cell," we must frankly state that in none of our tissue cultures were cells of this type observed. We were unable to duplicate in tissue culture at the end of twenty-four hours the general cellular pattern seen in the original tumor. We did demonstrate that the rate of growth in tissue culture roughly parallels the grade of the tumor, but the cellular appearance in twenty-four hours does not resemble the original tumor. A matter of considerable

interest from a clinical point of view is that benign tumors do not show activity in tissue culture, but malignant tumors, irrespective of the grade, will show signs of growth in twenty-four hours. This is most significant, and this medium might be added to our diag-

FIG 5

nistic data as a reliable method of deciding between benign and malignant tumors which, with our present equipment, may be incorrectly interpreted, often with unfortunate consequences to the patient. Regardless of the qualifications of the surgeon and pathologist, there is occasionally a case in which it is impossible to decide between a benign and malignant tumor with our present equipment, and in this group this new procedure might throw light. The suggestion made in the present study that the degree of malignancy of a human tumor may be related to the degree of activity it exhibits in tissue culture can probably be verified to best advantage by fur-

ther study. If a large number of such tumors were cultured and their activity at twenty-four hours were related to the pathologic diagnosis as well as to the postoperative history of the patients, significant information might be secured. If it should be confirmed that there is a relation between the degree of malignancy of a tumor and the degree of its activity in tissue culture, this might well develop into a practical diagnostic and prognostic aid to the clinician when dealing with certain types of tumors now difficult to classify.* A group of hospitals might maintain a tissue culture unit where samples of such tumors would be cultured as a matter of routine procedure, and within twenty-four hours the information thus secured would be available to add to that obtained from the usual modes of diagnosis.

• • •

I wish to acknowledge the courtesy of the Department of Biology, Washington Square College, New York University, for permitting me to conduct these experiments in their tissue culture laboratories.

* In following the above plan the perfusion pump described by C. A. Lindbergh in an article entitled "An Apparatus for the Culture of Whole Organs" (*Journal of Experimental Medicine* September 1 1935) might prove a diagnostically helpful apparatus.

BEFUDDLED LEGISLATION

A lot of befuddled legislation is being presented for passage in Congress these days and in our state legislatures, remarked Dr. Eben J. Carey, dean of medicine at Marquette University, in a recent address at St. Paul. All of it is based on the premises that the cost of medical care is too high in America and that medical care is inadequate.

I challenge both premises, he declared.

Americans are the healthiest people ever seen any time, anywhere. Their health depends upon healthy minds and souls as much as upon healthy bodies.

You cannot go out and buy five dollars' worth of health. And by the same token, you cannot purchase health by immense appropriations of money if, at the same time, you take away the dignity and rights of the human being.

THE RADIO HATH CHARMS

A healthy man must feel unhappy when he listens to the medical ballyhoo on the radio and realizes how easily, surely, and pleasantly he could be cured of many interesting ailments, if he only had them.

"SUFFER LITTLE CHILDREN"

The average couple seeking relief from sterility in the year 1920 had about a 20 per cent chance of accomplishing their desire if they were fortunately able to consult one of the half dozen physicians in this country who were at that time devoting particular attention to the subject. In the hands of other doctors, including eminent gynecologists and urologists, the likelihood of success was only half as great. Today there are many groups of expert workers whose percentage of cures ranges from 40 to 50. It would seem, remarked Meaker and Vose in the *J. A. M. A.*, that the profession has some right to congratulate itself on this striking improvement in the management of a problem which is vitally important in the lives of more than 2,000,000 American homes and consequently, in the aggregate, of no small importance to the social and economic welfare of the nation.

LUCKY, ONLY THREE

SUPPORTIVE THERAPY IN BRONCHIAL ASTHMA AND VASOMOTOR RHINITIS

JOSEPH S. STOVIN, M D, New York City

THE theoretic importance of protein desensitization has in recent years tended to overshadow the equally important consideration of correcting an underlying physiologic and biochemical imbalance so frequently manifest in the bronchial asthma patient. The desirability of broadening our concept of asthma therapy to include treatment of the "biochemical lesion" is emphasized in current researches of various investigators.

Witts¹ discusses the various problems of asthma therapy and concludes that "The detection of allergens is very different from the cure of asthma. The soil in which asthma develops is more important than the seed which induces the attacks, and future advances appear more likely to come through measures destined to modify the soil than through discovery of more and more allergens capable of exciting the paroxysms."

Careful inspection of the "soil in which asthma develops" is, of course, the concern of every physician who is confronted with the problems of this malady. However, as stated earlier, the study of the patient has too often been confined principally to the search for offending allergens both in the external and internal environments. Although in my experience desensitization, as well as attention to infective foci in the paranasal sinuses, has resulted in gratifying improvement in a fair percentage of patients, nevertheless one cannot escape the conviction that such procedures fail to bring the desired degree of relief in the average patient.

The Asthma Research Council,² after five years of investigation, conclude that the results of protein desensitization and vaccine therapy have not proved sufficiently successful. It was found that results obtained by general treatment without specific desensitization were at least as good as results of general treatment combined with specific desensitization and better than those of specific desensitization alone.

In harmony with the reports of Sangorgi³ and de Bersaques and Berat,⁴ who noted disequilibrium and instability of the neurovegetative system in asthma, is the marked relief observed after stellectomy by Leriche and Fontaine^{5,6} and after resection of the posterior pulmonary plexus by Reinhoff and

Gay.⁷ Numerous other workers have likewise effected relief of asthmatic attacks by interruption of nervous pathways.

That the problems of asthma and vasomotor rhinitis have been studied in a great variety of other ways is encouraging evidence of a determination to search beyond the now obvious phenomena of sensitivities to certain environmental factors and to attempt to elucidate the underlying mechanism. Disordered biochemistry was found in nearly every asthma patient studied by Clarkson.⁸ Although he does not go into the exact nature of the chemical disorders, his findings are of interest when viewed in the light of the close interrelationship between electrolyte balance, water metabolism, hormonal influences, and the activity of the autonomic nervous system.

Recent developments in the therapy of asthma and vasomotor rhinitis strongly suggest that the ailments may be, in part at least, manifestations of an imbalance in the body between the cations sodium and potassium. Stoesser and Cook⁹ noted that a high intake of sodium chloride tends to precipitate asthmatic attacks and that the severity of attacks can be influenced by shifts in the sodium chloride content of the diet. In a later report these same workers¹⁰ describe the successful use of a low sodium chloride diet combined with administration of pitressin and potassium chloride to reduce the frequency and severity of asthmatic paroxysms. They attribute the improvement largely to depletion of sodium chloride—pitressin, in spite of its antidiuretic action, causing an increased output of sodium chloride. Potassium chloride was administered coincidentally with the pitressin therapy and the reduced sodium chloride intake, and, although they apparently attach no significance to it, it seems probable that the potassium intake, as well as the sodium depletion, exerted an influence on the disordered chemistry.

With regard to vasomotor rhinitis, Kaplan¹¹ believes that in itself it "is not an allergic state, but is the result of faulty fluid and sodium balance. In this state abnormal permeability is often present and the patient may become sensitized to allergens which from time to time penetrate the permeable membranes." He obtained favorable results

in vasomotor rhinitis by depleting the sodium and increasing potassium and calcium in a dissociated form by the administration of acidifying agents. His capsule contained potassium chloride, 2 grains, which was given three times daily and increased to 3 or 4 capsules at each dose. It is very interesting to note that his favorable effects were achieved by small doses of potassium.

Rusk and Kenamore¹² treated urticaria with potassium chloride, finding that it acts like adrenalin in relieving symptoms. In an attempt to evaluate the relative efficacy of various salts of potassium, Bloom¹³ confirmed the finding that a salt-free diet is beneficial in decreasing the severity of asthma and found that simultaneous administration of potassium iodide "practically eliminates severe asthmatic attacks." He states that the patients are not cured but that the beneficial effects obtained by the combination of the salt-free diet plus potassium iodide are greater than would be obtained by the use of either regimen alone.

Potassium iodide, which has long been used in the supportive therapy of bronchial asthma and also in vasomotor rhinitis, has, in my experience, produced marked effects in many patients. The relief noted in asthma has seemed to extend beyond the liquefying of mucus and the facilitating of expectoration. Bloom did not obtain improvement in a group of 10 patients with chronic persistent asthma after the use of potassium chloride, which was the only potassium salt other than the iodide reported in his preliminary paper as being tested in asthma. However, in hay fever, urticaria, food sensitivity, and other allergic manifestations, potassium chloride produced marked relief, and a combination of the acetate, bicarbonate, and citrate salts proved almost equally effective.

In view of the frequent failure of specific desensitization to achieve the desired results in asthma and vasomotor rhinitis (especially in patients manifesting symptoms of each) and in view of recently reported researches on the beneficial effects of undertaking an alteration of the existing electrolyte balance, I have for some time been treating these patients with the latter purpose in mind.

In addition to any local therapy which may be indicated, the regimen I have adopted comprises a diet that I call a "high-protein, low-sodium, antiretentional diet." It is similar to the diets used for edema in cardiovascular disease. If the patient is underweight or if it seems undesirable for him to lose weight, the calories are increased. Most

patients lose weight on the diet, but fortunately this is not unfavorable to most of them.

To the patients suffering from bronchial asthma with no associated vasomotor rhinitis, the potassium is given in the form of potassium iodide and potassium bicarbonate. To patients who have vasomotor rhinitis with little or no associated asthma, I give potassium in the form of potassium chloride.

Since the response to this therapeutic regimen depends upon close adherence to the dietary prescription (providing for a low sodium chloride intake), it is important that the patient be instructed to avoid all foods on the "forbidden" list. Attempts to secure the patient's cooperation, in spite of the notorious unpalatability of salt-free meals, are important. The available salt substitutes have not proved satisfactory in significantly improving the palatability of foods prepared without the use of sodium chloride. Tests are now being made with various substances which show promise of correcting this fault of the low-salt diet, and a later report will describe the results of this phase of the study in greater detail.

The following cases are illustrative of the management of, and the results obtained by, the use of potassium and regulation of the diet in asthma and vasomotor rhinitis.

Case Reports

Case 1—A woman, aged 57, weight 180 pounds, had bronchial asthma for thirteen years. Relief was obtained only by self-administration of large amounts of adrenalin. She was placed on the high-protein, low-sodium, antiretention diet and was given potassium iodide (3 grains) and potassium bicarbonate (4 grains) every two hours. During the first month she lost 10 pounds. Her attacks were lessened in severity. She still required adrenalin but in much smaller amounts. At the end of three months there was a marked improvement, and she was kept on the same regimen indefinitely.

Case 2—A woman, aged 35, with a strong family history of allergy, had vasomotor rhinitis as far back as she can remember. She had several sinus operations with no improvement. Recently she had had mild asthmatic attacks. She reacted positively to timothy and for the past few years has received desensitization injections with good results. She was given potassium iodide (3 grains) and potassium bicarbonate (4 grains) every four hours. During the hay-fever season this dose was replaced by potassium chloride (10 grains) every four hours. The asthma disappeared entirely. She was entirely free of hay-fever symptoms, but this may have been due to the successful desensitization as well as to the potassium chloride.

Case 3—A man, aged 35, had a history of asthma for many years. During the past five years he had several sinus operations, each followed by slight relief from asthma. He obtained relief from epinephrine or ephedrine. Removing sodium from his diet and giving him potassium iodide (3 grains) and potassium bicarbonate (4 grains) every four hours resulted in a marked improvement. At the end of a month the cough and wheeze were still present but only mildly.

Case 4—A woman, aged 29, had asthma for many years. A pan-sinus operation several months before gave no improvement. When she was placed on the diet and given potassium iodide (3 grains) and potassium bicarbonate (4 grains) at four-hour intervals, there was a marked improvement. The cough became looser and more productive at first. At the end of one month it was greatly lessened. She lost 5 pounds during that period.

Case 5—A man, aged 38, had a positive family history and had asthma and vasomotor rhinitis for many years. He was placed on the diet and given potassium iodide (3 grains) and potassium bicarbonate (4 grains) every two hours. The paroxysms became less in frequency and severity and the sputum more liquid. The nasal symptoms were unchanged, but later, on changing to potassium chloride (10 grains) every four hours, there was a noticeable improvement, the membranes becoming drier and deeper red.

Case 6—A woman, aged 35, had a strongly positive family history of asthma and hay fever. All skin tests were of no avail, and she was not positive to any of the pollens. She had vasomotor rhinitis for many years and recently had acquired asthma. She was placed on the diet and was given potassium iodide (3 grains) and potassium chloride (4 grains) at two-hour intervals. After several weeks her wheezy, nonproductive cough became productive and finally abated. Her nasal symptoms did not improve until she was given potassium chloride (10 grains) every four hours.

Comment

The comparative efficacy of this regimen, as contrasted with the continued and often permanent use of epinephrine and epinephrine-like drugs, seems deserving of brief discussion. The initial efficacy of epinephrine in allaying asthmatic paroxysms is often dramatic, but with continued use many patients develop an epinephrine "fastness," after which its effectiveness progressively diminishes, necessitating the use of larger and larger amounts to produce relief. This in itself is an indictment of the practice of encouraging self-administration of epinephrine by patients. In addition, epinephrine should be more widely recognized as a dangerous drug which should custo-

marily be employed only under medical supervision.

A possible explanation for the epinephrine "fastness" which develops after prolonged use of the drug is suggested by the observation of Rusk and Kenamore¹² that "effects attributed to adrenalin are actually effects produced by potassium migration which adrenalin causes." It seems logical then that after continued use of the drug the electrolyte balance may be sufficiently upset to interfere with the potassium migration, the customary dose of epinephrine then fails in its effectiveness.

In marked contrast to the diminishing effectiveness of epinephrine is the sustained and often increasing effectiveness of the supportive therapy—potassium administration and sodium chloride restriction—described above. The amount of potassium salts administered daily was purposely low in the belief that a more lasting improvement could be achieved by gradual correction of the underlying biochemical and neurovegetative imbalance than by an attempt to correct abruptly a condition that had presumably been developing over a period of years or months. Criteria for determining in advance the dosage that will be expected to produce optimal results in individual cases have not yet been established to my satisfaction. These factors are still being studied and will be reported later.

Conclusions

The use of a diet rich in protein and acid ash and low in sodium chloride, combined with the administration of potassium in the form of potassium iodide and potassium bicarbonate, has proved effective as supportive therapy in the treatment of bronchial asthma. A similar diet combined with the administration of the chloride salt of potassium has given excellent results in the general treatment of vasomotor rhinitis with no, or only slight, associated asthma.

EXPANDING USE OF SULFANILAMIDE COMPOUNDS

The expanding usefulness of sulfanilamide and its derivatives, sulfapyridine and sulfathiazole, is revealed in twelve articles in the January 25 issue of the *Journal of the American Medical Association*, dealing with the three drugs. The same issue also carries an announcement by the Association's Council on Pharmacy and Chemistry of the acceptance of sulfathiazole for inclusion in New and Nonofficial Remedies and a report on an analysis of the drug.

Of particular importance is a paper which reports that sulfapyridine seems to be more applicable to the comprehensive treatment needs of gonorrhea than does sulfanilamide and another paper in which it is pointed out that the various sulfonamide drugs have produced encouraging results in the treatment of subacute bacterial endocarditis. This condition, involving inflammation of the membrane lining of the heart, until recently was considered to be generally fatal, and all methods of treatment had been adjudged ineffective.

A hopeful outlook for another condition involving the heart is reported in another paper, wherein it is stated that infections of the pericardium may be susceptible to treatment with sulfonamide compounds.

Still further evidence of the value of sulfanilamide in the treatment of actinomycosis is reported in another paper. This condition is a chronic infectious fungous disease of cattle, sometimes transmitted to man and characterized by the formation of lumpy tumors on the jaws and tongue. The fungus may develop in the viscera, bone, and skin, as well as in the mouth and jaws.

Physically induced fever enhances the value of these compounds in the treatment of subacute bacterial endocarditis.

In infancy and childhood, Drs Stewart C Wagoner and William F Hunting, Cincinnati, report that "sulfathiazole is as effective as sulfapyridine in the treatment of pneumonia."

Dr Charles K Friedberg, New York City, in a paper discussing sulfapyridine treatment in lobar pneumonia associated with leukopenia, points out that the presence of a low, white blood cell count should not contraindicate the use of sulfapyridine. He says that although it is known that sulfapyridine itself is capable of bringing about leukopenia the latter condition also may be associated with pneumonia and that when this is true the mortality rate is unusually high. He says that the danger of sulfapyridine leukopenia is relatively slight and that because of the effectiveness of the drug in the treatment of pneumonia its use is particularly indicated in severe cases of the latter disease.

In a discussion of the effective use of sulfanilamide in the treatment of actinomycosis, Drs Leonard Dobson, Emile Holman, and Windsor Cutting, San Francisco, report 3 cases, 1 involving infection of the jaw, 1 of the chest, and 1 of the abdomen. All of them were cured and the administration of sulfanilamide seemed to be the

deciding treatment agent. Their treatment of the cases also included the use of x-rays.

As to gonococcal infections, Drs. C J Van Slyke, R. R. Wolcott, and J F Mahoney, Staten Island, New York, report the results of their investigations of sulfapyridine in the treatment of such infections and compare the adaptability of sulfanilamide and sulfapyridine to the treatment needs of the disease. As a result of a study of 300 cases they say they prefer sulfapyridine. The cure rate, they report, approached 85 per cent for patients who had not received previous chemical treatment and 70 per cent for those who had failed to benefit by earlier sulfanilamide treatment.

Dr Morris H Nathanson, Los Angeles, reports that as the result of a study it was found that sulfanilamide and sulfathiazole diffuse into the pericardial sac. Because of this, he says that since infection of the pericardium may be due to organisms such as the pneumococcus, streptococcus, and staphylococcus, which are susceptible to the sulfonamide compounds, these drugs should be indicated in pericardial inflammations due to these organisms.

In a discussion of the present status of the treatment of subacute bacterial endocarditis, Drs S S Lichtman and William Bierman, New York City, state that among 200 cases of subacute bacterial endocarditis due to *Streptococcus viridans* and nonhemolyticus, collected from the literature and the records of the Mount Sinai Hospital, in which the sulfonamide drugs were administered, recovery occurred in 12, an incidence of 6.0 per cent recovery. Among 43 patients treated with a combination of one of the sulfonamide compounds and heparin 5 recovered, an incidence of 11.5 per cent recovery. Among 24 patients treated with one of the sulfonamide compounds combined with physically induced fever, 4 recovered, an incidence of 16.0 per cent recovery.

Drs Bierman and George Baehr, New York City, report the apparent recovery of 2 patients with subacute bacterial endocarditis by treatment with sulfanilamide and artificially induced fever.

Drs George B Craddock and Russel V Bowlers, Richmond, Virginia, report the effective use of sulfapyridine in the treatment of a recurrent case of meningitis (inflammation of the membranes enveloping the brain and spinal cord) occurring four times within a year in the same patient. "As far as we have been able to determine," they say, "there have been no cases of recurrent pneumococcal meningitis reported, this is probably due to the high mortality of this disease before the sulfapyridine era. Previous to the use of sulfapyridine, nearly all patients died before they could recover and suffer recurrences."

In another report Drs Joseph F Sadusk, Jr, and Aage E Nielsen, New Haven, Connecticut, report the recovery of a patient from the highly fatal meningitis due to *Staphylococcus aureus* following the administration of sulfathiazole.

COMMON GLAUCOMA OPERATIONS

Analysis Based on Histologic Findings

T L TERRY, M D , Boston

EACH operation designed to relieve glaucoma can affect the eye in more than one way. Success may depend on some subsidiary, perhaps unobserved effect. For example, every eye surgeon sees instances of reduced intraocular pressure following operations designed to establish artificial drainage even when there is no evidence that filtration occurs. In Table 1 an attempt is made to evaluate the full possible effect on the eye of various operations. Because of differences in opinion concerning the exact effect of many operations, one would expect considerable disagreement on the evaluations. Even with adjustment of the table to satisfy each observer, it is obvious that a glaucoma, relievable by any operation that would break the vicious cycle, would respond to any one of the many operations that allow aqueous to escape.

Paracentesis is usually of temporary value. Occasionally a filtering channel is obtained accidentally, in which case this operation is as permanently successful as an Elliot trephine. A paracentesis is valuable especially in association with active uveitis, since it is desirable to avoid any more extensive surgery in the face of inflammation. It is interesting to note that prolapse of a small knuckle of iris into the wound—which can occur—tends to produce a

Read by invitation at the Annual Meeting of the
Medical Society of the State of New York, New York
City May 7, 1940

recurrence of the glaucoma from postoperative synechia (Fig 1)

Little need be said concerning the curative effect of iridotomy in iris bombée if performed before anterior peripheral synechia has formed

Just how iridectomy is of value in acute glaucoma is not obvious. Instances of acute glaucoma cured by intensive use of miotics or by paracentesis alone suggest that the iridectomy is of value by emptying the anterior chamber and breaking a vicious cycle. Few iridectomies are really basilar, since $1\frac{1}{2}$ mm or more of iris is usually left behind. If the angle is open, one may safely insert a keratome into the anterior chamber at the root of the iris or make a section into the depth of the angle with a cataract knife. If an anterior peripheral synechia of any appreciable width is present, however, in inserting a keratome for a true basilar iridectomy one cannot avoid penetration of the posterior chamber. This penetration often involves injury to the lens, especially when a keratome is used. If the iris is normal at the time of the iridectomy, the iris stroma shows no tendency to heal, but permanent sealing of the cut blood vessels does occur. Following uveitis or accompanying long-standing glaucoma, the iris becomes fibrosed. Holes made in a fibrosed iris tend to close. This tendency accounts for closing of iridotomies in some instances. The cut edge of the iris may become adherent to the tissues at the site of the scleral or corneal wound (Fig 2).

TABLE 1 INDICATIONS OF POSSIBLE EFFECTS OF
VARIOUS OPERATIONS TO RELIEVE GLAUCOMA

[illegible]

FIG 1 Prolapse of small portion of int, anterior border layer, and stroma into paracentesis wound

FIG 2 Anterior synechia formed by adherence of cut edge of iris to posterior surface of corneal wound following iridectomy

FIG 3 Posterior sclerotomy Wound made by diathermy Note that wound has truncated cone shape Retina destroyed farther from wound than choroid Vitreous present in wound

Posterior sclerotomy, of value where other measures fail or are impossible, can be used not only to temporize or prepare for a filtering operation where there is no anterior chamber but also to give almost immediate comfort in instances of hopeless general illness associated with congestive glaucoma. When no local anesthesia is effective and no general anesthesia can be given, this operation can be done with a minimum of pain. If one desires to obtain a filtration for some period of time through the sclerotomy wound, it is wise to make the opening with diathermy (Fig 3). The incision can be made behind the ora serrata without fear of postoperative separation of the retina, since the diathermy also closes the edges of the hole made in the retina. The opening through the sclera can be made with a trephine if desirable. If the entire operation is done with a cutting instrument, it is preferable to open the eye through the pars plana of the ciliary body to avoid puncturing the retina. It must be remembered that the flow of fluid through the vitreous following a posterior sclerotomy causes the vitreous to liquefy.¹

With opinion based on the present understanding of pathologic principles, it appears that a Barkan² goniotomy would tend to give only temporary drainage, since any incision from the anterior chamber into Schlemm's canal through sclerosed iris angle would tend to close. This theory depends on the assumption that there is a sclerosis of the iris angle meshwork, a condition found in instances of early glaucoma especially in association with exfoliation of the lens capsule (Fig 4). However, only longer experience with this operation and histologic study of eyes subjected to the operation can demonstrate the ultimate results.

In glaucoma caused by a markedly intumescent lens or by a lens dislocated into the anterior chamber, removal of the lens is the operation of choice, but in each instance every effort should be made to reduce the pressure to

normal before extracting the lens. If a patient with glaucoma has a cataract, it is preferable to remove the cataract first, providing the pressure can be brought down temporarily. Often no other operation is needed. If the operation to relieve glaucoma is done first, the corneal section for cataract extraction must be made obliquely or intracorneally to avoid destruction of the filtering bleb.

The only pathologic specimen of cyclodialysis available at the Massachusetts Eye and Ear Infirmary shows the lens tilted and pushed away from the region of operation (Fig 5). Elasticity and muscle tonus of the ciliary body and iris appear to be the only force, constantly present, that tends to keep a cyclodialysis wound open. Were this force sufficient, Troncoso³ would have had no incentive to design the operation in which magnesium foil is introduced into the wound to keep the tract open.

All successful filtering operations, opening a channel to drain aqueous into subconjunctival and episcleral tissue, appear to give relatively similar results except in iris inclusion operations where remains of pars iridis retinae are always present although the iris stroma disappears. Operative wounds may close through scar tissue growth from adjacent structures. Fibrous tissue may arise from the iris, especially if a newly formed, vascularized membrane is present on the iris surface (Fig 6).

This condition is found in hemorrhagic glaucoma and glaucoma secondary to malignant melanoma of the uvea, secondary to long-standing separated retina, and rarely secondary to retinoblastoma. Filtration wounds are at times blocked by prolapse of iris, part of ciliary process,⁴ hyperplasia of ciliary process, lens (Fig 7), epithelization of the anterior chamber, vitreous, and blood clot. When blockage occurs, a subconjunctival decapitation of the bleb in some instances may turn a failure into a success. These operative wounds are areas of weakened resistance

through which toxins and bacteria themselves may gain entrance to the eye from purulent conjunctivitis.

Based on the theory that sclerosis of vortex veins is responsible for certain types of glaucoma, Sondermann⁵ devised a sclerotomy over the ciliary body, performed by means of a trephine, to make an opening through which blood vessels from the ciliary body can anastomose with episcleral vessels. In common with cyclodialysis and probably with goniotomy, it may traumatize the ciliary body sufficiently to produce temporary cessation of function. The kidneys at times cease to function after a sudden decompression of the bladder following prolonged retention of urine at a high pressure incident to enlarged prostate. Any decompression operation on the glau-

FIG 5. Composite diagram from various sections of eye on which cyclodialysis had been done. Disinsertion of the retina and vitreous hemorrhage present. Note position of lens. It has been tilted backward and pushed away from region of operation.

comatous eye may have a similar result.

Operations designed to retard the formation of aqueous consist in destructive injury to the ciliary body. Such an injury can be accomplished by means of diathermy, either by use of Walker points or by the flat electrodes of Weve. Until more knowledge of the results is available, no definite conclusions are possible.

EARLY SIGNS OF SERIOUS GYNECOLOGIC LESIONS

JAMES RAGLAN MILLER, M D , Hartford, Connecticut

MY TOPIC implies that the specialist should point out in a frankly critical manner those mistakes that are commonly made early in the course of disease—those errors of omission and commission which delay or make difficult the application of therapy that would otherwise be curative. More can be learned by studying our failures than by boasting of our successes. I shall consider a few examples that illustrate particular points. These are chosen from cases of prolapse of the uterus, pelvic infection, and cancer which stress some of the methods of early recognition.

We speak of general practitioners and specialists as if sharply drawn lines could departmentalize the patient. Dangers lie in that kind of thinking, for frequently two or more systems of the body are affected by a single cause and we have learned from bitter experience that obvious and adequate explanations of symptoms in one system may distract our attention from early and serious lesions elsewhere.

Any specialist who attempts to criticize the general practitioner should do so with a profound sense of humility, appreciating that it is more difficult to diagnose early lesions than full-blown disease. The criticism I have in mind, however, is not that the first examining physician fails to recognize early and rare lesions but that he fails to make use of his five senses and to apply to the problem of diagnosis the clinical resources at the disposal of every well-trained medical graduate. I consider it most dangerous to make light of a patient's story without adequate examination, for her symptoms may be the earliest warning signals of serious disease. I shall later give examples to illustrate these criticisms.

I realize that all of this must be familiar to you, and I feel you may be disappointed that I cannot bring to you new methods and formulas by which these mistakes can be avoided. I may hope, however, that frank discussion of errors that I have made as well as others that I have observed may help to avoid falling into the same difficulty in the future. Most of all I should hope to encourage the development of a diagnostic habit.

Read by invitation at the Annual Meeting of the Medical Society of the State of New York, New York City, May 9, 1940.

Obstetrician and gynecologist, Hartford Hospital

that takes nothing for granted even when the doctor is tired and the patient is a chronic complainer.

Consultations should be recommended as needed, but consideration must be given to the patient's financial resources and to the relative importance in her life of the given lesion. There are certain situations with which you are familiar where it is much more humane to avoid any serious effort at making an accurate diagnosis and to suppress for the time being your scientific curiosity. I mention this merely to be sure that in our scientific discussions we do not lose a sense of proportion and forget that we are dealing with human beings. Lest our sympathies unduly influence our judgment, let us be careful not to deny any patient the help that today can be given safely simply because we have in mind the failures and the high mortalities of an earlier period.

Many a prolapse of the uterus comes to the specialist for operation in a condition that makes him wish that he had seen the patient earlier. Some of these instances are due to the patient's own neglect, but I recall cases of prolapse with cystocele which have been carried on for years with inadequate local support, suffering repeated attacks of so-called bladder trouble. It appears that most medical men think of prolapse of the uterus in terms of backache and of mechanical inconvenience to the patient. I would suggest that you consider, more seriously than has been done in the past, the effect on the urinary system of continued distortion of the trigon of the bladder and of the ureters caused by prolapse and cystocele. Adequate repair should not be postponed until the patient presents herself as a poor risk because of age and repeated attacks of urinary infection. As a recent example I cite Mrs. E., aged 51, who was referred by her physician for repair of a second-degree prolapse with moderate eversion of the vagina and cystocele. She was a hard-working housewife, six months in the menopause, and had recently had a "cold." Her urinary tract showed marked dilatation and a proteus infection which explained her "cold." Repair by vaginal hysterectomy and continued treatment of her urinary infection have completely relieved her

These kidney tract infections should be recognized early, for it is not a difficult thing to get a catheterized specimen under sterile precautions and have a culture made. No gynecologist will do elective repair work in the face of an active urinary tract infection, and family physicians who refer patients for operative treatment at some distance can avoid embarrassment and save the patient much time and money by recognizing and treating the complicating urinary tract infection.

A common mistake often seen is the application of caustic or cauterizing agents to the cervix before the patient is sent for consultation or for surgery. We should remember that any caustic agent causes a low-grade infection in the presence of which elective operation should not be undertaken. Such a cauterization should postpone operation for at least a month. This may be slightly over-conservative, but the patient who has elective surgery performed has a right to expect that the most ideal situation will prevail.

Before leaving this subject may I refer to strictures of the female urethra. While this is not an early sign of serious gynecologic disease, it is an often missed diagnosis. It is easily made and easily treated, and one has but to be alert to the possibility. In the treatment of strictures of the female urethra I strongly recommend the use of male urethral sounds.

The importance of conservatism in the treatment of acute pelvic infections has been generally accepted. Few gynecologists or general surgeons will open the abdomen if they are reasonably certain that an acute infection arises from the pelvic organs. Granted that appendicitis can be ruled out, conservative methods are the rule, particularly at the onset of infection in the handling of which the newer sulfanilamide preparations have been found so effective. These are particularly useful in infections with the streptococcus, gonococcus, colon, and Welch bacillus—organisms that produce the great majority of pelvic infections. From what I can observe there seems to be little need to urge the general practitioner to make use of these drugs, rather one should advise caution in using them thoughtlessly for any condition showing febrile reaction. The one particular point I wish to emphasize in the field of pelvic infections is the danger of vigorous cauterizing of the cervix in the presence of acute infection. Many instances of serious and even fatal infections have been recorded, lighting

up fatal infections by an overvigorous local treatment. Such a case is the following.

Mrs. M. was a manicurist who had had 1 child fifteen years previously. Ten years before admission the right tube and ovary had been removed. In the face of a positive urethral smear for gonorrhea, which her physician had himself taken one week previously, her cervix was cauterized. Within three weeks she died on our wards from a purulent peritonitis salpingo-oophoritis arising from a broad ligament abscess, which at autopsy was clearly an extension of the necrotic and infected area of the cauterized cervix.

This physician was a graduate of a grade A medical school and he had not learned the necessity of avoiding local treatments in the face of acute infection.

May I call to your attention the great importance of an accurate history of the beginnings of pelvic infections. It is characteristic that gonorrheal infection ascends to the peritoneal cavity at, or immediately following, a menstrual period, whereas the gram-positive organisms and colon bacillus infections are more apt to follow an interrupted pregnancy. The physician who is closest to the patient at the time of onset can add greatly to the knowledge of the case by furnishing all significant data of the circumstances surrounding the onset of symptoms.

In this country syphilis is undoubtedly diminishing, and there are, no doubt, few physicians who have ever seen a primary chancre in the woman. I call to your attention an excellent monograph on primary syphilis in the woman by T. A. Davies, of London, who showed that 45 per cent of 584 primary genital chancres in women were internally situated. In fact 44 per cent of the entire series were located on the cervix. Now these chancres must be looked at to be recognized, and they do not remain there indefinitely. Consequently the physician who discovers a fresh case of syphilis in one of his male patients should promptly inspect every female contact. If he does so he may be rewarded by discovering an early case. I can think of no greater satisfaction that I have had in practice than of making one such discovery. I was able to prove the diagnosis by dark-field examination and to have the patient under adequate treatment before systemic infection, as shown by a positive Wassermann, had taken place. The Biblical admonition in this instance is "Seek and ye shall find."

We can perhaps be of most service in discussing our general topic by spending most

of our time on the early diagnosis of cancer. Unlike cancer in the genital tract of the man, female genital cancers are predominantly accessible. It is to be noted that one-half of the predominantly accessible female cancers are those in the genital tract, constituting 21 per cent of all cancers in women. When we consider these facts the gynecologist often feels that there is little excuse for the great delay in making the diagnosis that he unfortunately observes.

In Willmantic, Connecticut, a realistic group of physicians, after surveying their hospital cancer material, made these observations. In gynecologic cancer the time elapsing between the first symptoms and the first visit to a physician averaged three months, the time elapsing between the first visit to the physician and hospital admission averaged two and one-half months. In the group where there was no delay 66 per cent were "operable", in the delayed group only 30 per cent were "operable", and they noted, furthermore, that for the whole series 31 per cent had been given poor medical advice. I am convinced that physicians generally do not appreciate the need for speed in placing cancer patients under treatment. It has helped me to visualize this need by recalling the figures, worked out in Boston, that the prospect of five-year arrests in cancer of the cervix diminishes on the average about 4 per cent each week that the patient is delayed in getting under treatment.

The early symptoms of cancer of cervix and fundus are well known to you all and can be summarized in two words—atypical bleeding. This bleeding may occur without warning and without exertion, or it may occur following coitus or douching. All such instances of bleeding are by no means cancer, but the physician must satisfy himself as to the origin of such bleeding. The public is learning this lesson rapidly and is bringing the problem of early diagnosis, of excluding the cancer diagnosis in particular, to the physician, and he is expected to take the matter seriously.

I cannot proceed further without paying my respects to the most dangerous practice of hormone treatment in the cancer age without first proving the absence of cancer. I think the hypodermic syringe filled with the latest hormones is one of the most deadly weapons that has been placed in the hands of the medical profession. This quackery, I am sorry to say, is thoughtlessly practiced by members of our profession and is undoubtedly

responsible for the delay in the diagnosis of many cancers of the uterus. Let there be no misunderstanding on this point. I would not stand in the way of any legitimate experiments or treatment with hormones once the physician has assured himself by curettage or biopsy that he is not dealing with malignancy. After that I can trust the patient's limited resources to exert a restraining influence upon the scientific enthusiasm of the experimental hormonologist.

A recent address by Dr N T Root, of West Hartford, late president of the Hartford County Medical Association, summarizes the general practitioner's point of view concerning the cancer problem. To the general practitioner cancer is a small part of his work. Among 2,350 individuals seen by him in two years, only 36 were recognized as having cancer, though four others refused investigation of suspicious symptoms. The comparative rarity makes one forget the likelihood of occurrence. Symptoms may be adequately explained by some other diagnosis, or the early lesions may be entirely masked by an acute and temporarily more serious illness. Then, too, the general practitioner is close to his patient, and, while he is theoretically best able to detect early symptoms, it is more difficult for him to have a scientific attitude toward his old friends than it is toward strangers. It is particularly hard for him to suspect real illness in the chronic complainer. Dr Root felt that many general practitioners are unnecessarily discouraged once a diagnosis of cancer is made, feeling that the prognosis is hopeless, though in the light of present knowledge, and particularly in the case of gynecologic cancers, this attitude is quite unjustified. I quote his final paragraph verbatim: "It is a particularly opportune time for the general practitioner to take stock of his position in this important phase of his work, important not so much because of the number of cases that he sees, but because, as is so seldom true, his decision here is actually one on which life or death depends. He may make many mistakes in diagnosis or treatment in the course of a day on the average case, and his patient will get well in spite of him, but in this disease if he slips up, the fatal outcome may be justly attributed to him. At a time when the public is questioning the organization of medical men and the efficiency of the service which we are rendering, and when we are offering as the alternative to socialized medicine the reinstatement of the general practitioner as a keystone of the

practice of medicine, we must face the question as to whether or not, in this field, we are really giving the service the public and the rest of the profession have a right to demand."

Cancer of the vulva is not frequently seen. Its treatment is generally considered to be surgical with radical removal of the vulva and adjacent lymph glands. Leukoplakia and kraurosis are definitely considered precancerous lesions though they may turn out to be amenable to hormonal or vitamin treatment. For the present at least, our attitude should be to regard them with the utmost suspicion, and some experienced gynecologist should shoulder the responsibility of treatment. A simple removal of these precancerous lesions is easily done without shock, and certainly no case of leukoplakia of the vulva or of kraurosis should go more than three months between follow-up examinations.

One of the discouraging cancers in the woman is that of the ovary. We have learned, however, that many ovarian tumors, formerly called malignant, in reality are benign. These tumors cannot be distinguished clinically in the early stages when if they are malignant cure may be effected. We must rely on detecting enlargements of the ovary by repeated pelvic examinations in the cancer age. The public is coming to us in greater numbers than ever before for annual physical examinations, and every practitioner and gynecologist has many women who, because of a mild cancer phobia, come for regular pelvic examination. It is common practice for the gynecologist to record his objective findings, a habit that I commend strongly to the general practitioner if he does not do it already. It is desirable at times to appreciate that an enlarged ovary is actually growing according to the objective records. Cancer of the ovary is often slow in growing and should be more often cured. We must even be prepared to operate unnecessarily to catch the occasional early malignant tumor, for, as Schiller has pointed out, it appears likely that ovarian carcinoma does not start as a small group of malignant cells but rather occurs as a malignant transformation of neoplasm which hitherto had been benign. This concept indicates the need of prophylactic removal of ovarian growths in much the same manner that the surgeon must prophylactically remove adenomas of the thyroid.

Gynecologists have been much interested in the Schiller iodine test and in the Kolposcope for the diagnosis of early cancer of the cervix and especially for the differentiation of cancer from other lesions. Every general

practitioner should be reassured, however, by the observation commonly reported now by gynecologists of the widest experience, that these methods have not added much to the ability to detect early cancer. It is certain that early cancers can be observed by any properly bespectacled physician, provided he will bring to bear on the lesion adequate illumination and a consciousness of cancer possibilities. The iodine solution is an excellent disinfectant to use if he wishes to take a biopsy, and it will often call his attention to the fact that the cancer has extended beyond the area that naked-eye observation would indicate. The Kolposcope is of help only to the specialist who has wide experience in its use.

The following case histories will serve to illustrate matters that seem to me important.

Case Reports

L. M., aged 66, had consulted a general surgeon over one year previously for vaginal bleeding. He had performed a biopsy of the cervix, which was reported as chronic cervicitis, and she was reassured. After several months with continued bleeding she placed herself under the care of two general practitioners who treated her medically without success. The patient herself sought consultation of a specialist. Adenocarcinoma of the fundus was found and successfully treated with radium and panhysterectomy.

Comment—In this instance the surgeon went through the motions of ruling out cancer of the cervix but completely missed the cancer of the fundus. Not only he but two other physicians relied on the negative biopsy. The best pathologist cannot make a correct diagnosis unless significant tissue is submitted for the examination.

E. B., aged 43, in April had consulted a gynecologist who had advised hysterectomy because of a fibroid tumor. The advice was not taken, but under the encouragement of a general practitioner who acquiesced to nonoperative treatment the patient received x-ray therapy without improvement. In October, laparotomy disclosed an adenocarcinoma of the ovary of the pseudopsammoma variety, complete removal of which was impossible. She died fourteen months later.

Comment—Whenever a patient is encouraged to follow a course different from that advised by the specialist, the general practitioner must be prepared to shoulder the burden of the consequences. In this case no conference was held by her physician and her specialist, the patient being allowed to choose between conflicting opinions.

G. R., aged 48, had had regular periods until nine years previously, since that time they have been totally irregular. She was first given the "benefit" of hormone treatment by her general practitioner. When this failed she re-

sorted to osteopathy. Becoming discontented, she presented herself at the hospital with a Stage 2 carcinoma of the cervix.

E W, aged 45, was sent in promptly by her general practitioner with a history of three months intermenstrual bleeding. A prolapsed submucous fibroid, the size of a hen's egg, was excised. Death resulted from sepsis with pelvic cellulitis.

Comment—This case is mentioned to illustrate the danger of submucous fibroids that become strangulated and give rise to a virulent interstitial infection. Such instances are not infrequently seen in the menopause, and they should be handled promptly and with skill.

M B, aged 46, had never been pregnant. This patient came to her physician because of pain in the neck and shoulder. He gave her a complete examination and found a small area of leukoplakia on the cervix. The suspicious point about this leukoplakia was that it was adjacent to the external os. This physician showed fine judgment in referring her for diagnosis and treatment without applying any local cauterizing agent to the lesion. Biopsy showed an early carcinoma, and radium and x-ray treatment were given with every prospect of cure.

C A., aged 41, had never been pregnant. She was referred by her local physician because he found some polypoid masses in the cervix. An early carcinoma of the cervix of the transitional cell type was found on biopsy. Radium and x-ray treatment were given with every chance of permanent cure.

Comment—This case is presented to emphasize the fact that not a few carcinomas of the cervix develop within the cervical canal and that particularly in nulliparous women they may extend their growth upward and not appear at the portio until late in the disease. Several such instances have been observed in the last two years in the Hartford Hospital, and unfortunately

the diagnosis was missed on a number of occasions because the physician was not alive to this very possibility.

McM, aged 47, para I, has been inspected once a year because of a cancer phobia. One year previously the cervix had been clean except for a small erosion which had been treated with silver nitrate. No history of irregular bleeding or discharge had complicated her menopause. Inspection of the cervix, however, showed at this time an area of patchy leukoplakia adjacent to the external os. Schiller's test showed no iodine stain in this area, and a biopsy was taken which showed an early epidermoid carcinoma of the cervix. This lesion was thoroughly treated by radium and x-ray, and there is every prospect of a permanent cure.

Conclusions

1 It should be the aim of the general practitioner who first sees the patients to recognize early lesions that are suspected of being serious gynecologic disease, but he should apply no treatment that would seriously interfere with making a positive diagnosis.

2 No unusual skill or knowledge is called for in the early recognition of cancer in the woman. Cancer-mindedness and a willingness to examine completely are all that is necessary to bring most gynecologic cancers under early curative treatment.

In these times when the latest refinements of technic fairly bewilder us all, it is well to remember that early recognition of gynecologic cancer is astonishingly simple, yet Emerson has truly said "Nothing astonishes men so much as common sense and plain dealing."

NEW PNEUMOTHORAX FILM

"Artificial Pneumothorax in the Treatment of Pulmonary Tuberculosis" is the title of a new sound film edited by Drs. James S. Edlin, Sidney Bassin, and Walter Lichtenberg. The film is introduced by Dr. Kendall Emerson, managing director of the National Tuberculosis Association.

The film is a timely presentation, observes the N Y T & H A. Journal, in view of the great increase in the amount of compression therapy being carried on in the treatment of pulmonary tuberculosis. The narrator describes in a distinct, clear voice the elements of pneumothorax treatment and demonstrates the utility of this form. The legend includes an exposition of the various complications that may attend both the induction and maintenance of collapse therapy. The film also shows the actual collapse of the lung during the administration of care under fluoroscopic control. This is one of the most technically illustrative parts of the picture.

SPRING FEVER

The French philosopher Montaigne once said that each year he looked forward to spring as does the bridegroom to the bride, but when spring had arrived he felt like a septuagenarian who had married a young girl of eighteen.

These words were spoken about 350 years ago, but its truth is still obvious, observes the *Medical Record*. The only difference is that we explain the fact in another way. Many people who look forward to spring with joy are deeply disappointed because this season does not bring anything for them but unpleasant physical and mental feelings. They feel tired and weary, are fatigued and nervous, and complain of headache or stomach distress. They suffer from depressions which are quite new to them. In other cases a real feeling of fever is produced, culminating in a kind of spring ecstasy with a remarkable state of excitability, a strange happiness, and a sharpening of the intellectual creative powers.

ULCERATIVE COLITIS

FRANK H. LAHEY, M.D., BOSTON

ULCERATIVE colitis remains today one of the most distressing diseases with which we as physicians or surgeons have to deal. It is distressing to the patient because he or she has to endure a disease that not only seriously affects his health but, in a very definite percentage of cases, is one that results fatally. This disease is distressing to us as doctors because we lack real knowledge as to its cause and have no specific form of treatment for it. In spite of the admission of these two so undesirable facts, the situation with ulcerative colitis is not so bad as one might expect it to be under such unfortunate conditions. With added interest in this disease within the last five years, particularly between those surgeons and those physicians especially interested in gastroenterology, there have developed methods and measures whereby a majority of the patients with this disease (59 per cent in our hands) can be given either complete relief or a return to health with mild persistent bowel symptoms largely by means of dietary regimen.

The remaining group (41 per cent) of patients are made up of the mortality of the entire group, surgical and nonsurgical (16 per cent), and those patients upon whom it has been necessary to employ surgery.

There have been performed in the clinic 70 ileostomies for this disease with a mortality rate of 22 per cent. There have been 48 partial or total colectomies done in the clinic upon patients with this disease. These colectomies are made up of 14 partial colectomies in which there has been no mortality and 34 total colectomies in which there were 2 operative deaths. Of these 32 patients who recovered from the operation of total colectomy (including the rectum), 30 are well. One committed suicide some time after leaving the hospital, and 1 died of perforation between the stages of the operation.

There has been a variety of speculations as to the cause or causes of this disease such as amebic infection, vitamin deficiency, allergic reaction, and even the presence in the intestinal tract of a specific organism. Exclusive of the last, which can now be excluded as

nonexistent, two of these factors undoubtedly have a role in the existence of the disease—vitamin deficiency and allergic reaction. In the light of the experience that we have had it is unlikely that amebic dysentery and ulcerative colitis are even closely related diseases except as they express themselves by colonic ulceration and the resulting colonic discharges. They have quite different proctoscopic pictures, with the presence of a specific organism in one and absence in the other, and with at least more or less specific treatment in one and the complete absence of it in the other.

The clinical features of the disease need little discussion. The ulcerative process starts in the rectum and rectosigmoid in 90 per cent of the cases. It remains segmental in 10 per cent but in time will usually involve the entire colon. The ulcerative process penetrates the mucosal lining of the colon and at an early stage infiltrates the colon wall essentially to convert that structure into a fibrotic tube (Fig. 1). The x-ray findings are dependably typical, with early loss of haustral markings extending in the advanced cases to the so-called lead pipe colon in which the colon appears by roentgenologic examination as a rigid walled tube (Figs. 2 and 3a and 3b).

Remissions without apparent cause are of not infrequent occurrence. Serious temperatures with alarming systemic reactions are frequently associated with this condition, and loose movements in excessive numbers are often the most distressing complications of this disease from the patient's point of view. Hemorrhage from the bowel and perforation with peritonitis, while not common complications of this unhappy state, occasionally appear almost out of a clear sky to add further seriousness to a situation already a disturbing or even desperate one. Associated with the disease are quite typical proctoscopic findings, the ulcerative process involving all of the rectal mucosa as opposed to the proctoscopic picture of amebic ulceration in which there are areas of quite normal mucosa between the amebic ulcerations.

While I am particularly interested in discussing the surgical management of ulcerative colitis, I cannot limit myself solely to thoughts of technical procedures in those patients with ulcerated colons, since no mechanical surgical procedure can restore the func-

Read by invitation at the Annual Meeting of the Medical Society of the State of New York, New York City, May 9, 1940.

From the Department of Surgery, The Lahey Clinic, Boston.

FIG 1 Fibrotic colon of advanced case of ulcerative colitis. Note the contraction of the colon, with injection and ulceration still present in the cecum and strictured areas. A, blind ends, B, ileum.

FIG 2 A segmental area of ulcerative colitis between the arrows.

Chloride deficiency is often found in cases of diarrhea or profuse ileal drainage. Giving large doses of salt by mouth or by vein improves the patient's condition.

Opium is a useful drug for the control of exhausting diarrhea. Bismuth and kaolin may slow up the bowel action in some cases, while in others they seem to increase the number of stools. Adequate sedation for nervous patients is highly essential.

tion to a fibrosed colon of absorbing vitamins K and C, whether or not the fecal stream has been sidetracked by ileostomy. A food to which a given patient is allergically sensitive can, in certain cases, result in such activation of a previously quiescent colon that temperature elevations and rectal discharges of blood and pus can occur.

Whether or not surgery is required in a given case, adequate nonoperative measures are essential in all of them. A dietary regimen to supply the caloric needs of a patient hampered by fluid and fuel loss, as well as mineral and vitamin losses, must be supplied.

The diet for a patient with active ulcerative colitis and diarrhea should be low in residue, high in caloric value, and nonstimulating to intestinal peristalsis so as to permit slow passage through the small intestine and allow for adequate absorption. Boiled milk, eggs, and the refined cereals make up the basis of this diet, and meat can be used early as a low-residue food. Individualization is necessary because of the fastidious appetites and food idiosyncrasies frequently found in these patients and to which it usually pays to give consideration. This type of diet tends to be low in vitamins of the B, C, and D groups, and supplementary administration of these factors is usually necessary. Long-standing depletion, as well as poor absorption, needs to be considered in planning the dosage. Parenteral administration is often desirable.

The surgical treatment of ulcerative colitis today involves only two surgical aims—one, sidetracking of the fecal stream by ileostomy, the other, removal of a part of the colon (partial colectomy, 14 cases, no mortality) or total colectomy, including the removal of the rectum (34 cases with 2 fatalities). The employment of other surgical procedures, such as appendicostomy and cecostomy, has been practically abandoned by those with any considerable experience with this disease.

Ileostomy (70 cases, mortality 22 per cent) is employed either as a single procedure with the hope (1) that such a degree of resolution may be accomplished in the colon that it can again have its function as a normal fecal pathway restored by ultimate closure of the ileostomy (this has been done in 3 cases in our experience—all well) or (2) as a permanent procedure with the hope that such complete and permanent sidetracking of the fecal stream will result in such established quiescence of the colon that its later removal in part or entirety will not be necessary. This has been true in 4 of our cases.

While ileostomy is a part of any surgical procedure (fecal sidetracking alone or followed by colectomy), its employment in this disease occurs under two quite different conditions: (1) as an emergency measure in a patient in a more or less desperate state of intoxication and depletion and (2) as a deliber-

FIG 3a

FIG 3b

Figs 3a and 3b The typical lead pipe type of colon in an advanced, fibrotic process of long-standing ulcerative colitis

ate measure either preliminary to the later removal of the colon or as a complete procedure in an attempt to obtain quiescence of an activated colon, which activation has failed to be controlled by nonoperative measures

Dr Richard B Cattell (whose interest and contributions to this subject have far exceeded my own) and I have performed most of these 70 ileostomies in the clinic, and it has been definitely established in our minds that the successful surgical management of this disease has to do particularly with when and how ileostomy is done. As we have reviewed our experiences with ileostomy from time to time, we have been impressed with the fact that the decision for or against the production of an ileostomy is an extremely difficult one. Many conflicting psychologic factors are involved.

If ileostomy were not such an objectionable type of enterostomy there would be considerably less inclination to delay in the decision to perform it. One must admit, however, that with the liquid character of its fecal discharge it is managed with difficulty and at the best requires several changes of the bag daily. One must also admit that in many of the cases, at least for some time, there is considerable irritation of the skin about the wound from the liquid discharge. One must likewise consider that many of these patients

have been through several acute episodes with their ulcerative colitis from which they have successfully recovered, and this encourages them to hope with each episode that an ileostomy will not be necessary. Finally, one must appreciate that these patients' management is often in the hands of a medical man or gastroenterologist who feels on the one hand some justification in a risk taken to avoid the probable permanent presence of an unsatisfactory type of enterostomy and who on the other hand does not have the first-hand conscience prick which goes with the personal responsibility for the surgical procedure and its fatal outcome if it is done too late. Always in approaching the surgical treatment of this disease there will be this delicate psychologic balance swaying between saving these patients from a too early or perhaps unnecessary ileostomy and permitting him or her in this endeavor to advance to such a state in the disease that when ileostomy is ultimately done a fatality is quite likely to result. These remarks are not made with any critical intent concerning anyone but ourselves and rather to present frankly our convictions based upon this considerable experience from which we have largely learned to avoid these errors.

We are particularly fortunate in being an integrated group of gastroenterologists, surgeons, and roentgenologists working inti-

mately and tolerantly together, and we are hopeful that the presentation of our experiences and views may possibly save others, perhaps working as individuals, from making some of the mistakes that we have almost of necessity made in the acquirement of this experience

In a general way one may say that if an error is to be made as to the doing of an ileostomy in patients with severe ulcerative colitis it is better that it be done a little too early than a little too late. One can at least close the ileostomy at a later date should conditions justify it, while under the other conditions one only regrets that it was not done sooner.

If we are to make any real attempt to check the progress of a case of ulcerative colitis not progressing satisfactorily under nonoperative management and if we are to make any pretense of increasing the number of cases in which we can later close the ileostomy and restore the fecal pathway, we must employ ileostomy at an early stage and before the procedure is forced upon us by the unfavorable progress of the disease. If we wish to increase the number of cases in which possible closure of the ileostomy can even be considered, ileostomy must certainly be done at such a stage in the ulcerative colitis that the colon has not become rigid and converted into a fibrotic tube. It will be necessary to establish ileostomy in certain of the early segmental cases of ulcerative colitis. It will be necessary to establish an ileostomy in certain cases of ulcerative colitis in which infiltration of the colon has as yet not become marked and in which cases there must still be assumed the possibility that with continued medical management there well might be recovery without ileostomy from the immediate episode.

If we are to make greater progress than we have already made in this disease, we definitely must do a larger series of cases in which ileostomy is deliberately undertaken reasonably early in the disease with the hope of checking its progress and later restoring the fecal pathway by closing the ileostomy. An insufficient number of cases handled in this way has as yet been done so that one cannot definitely say whether or not this procedure has sufficient value to justify it. By this plan one would still medically manage those patients whose disease is tractable to medical management but do early temporary ileostomy in those patients whose disease tends to be intractable to medical management (41 per cent of all of the cases).

From these remarks one can see how necessary it is to have available the interest and judgment of men who are especially interested in this disease and who, based upon a considerable experience with it, can make these decisions for or against ileostomy and later for or against colectomy. As in other special diseases, but particularly in ulcerative colitis, the factors of experience and judgment have a great deal to do with its surgical mortality.

Since ileostomy in ulcerative colitis is usually done at a stage when the patient's progress in the disease is unsatisfactory, how it is performed also often plays a considerable part in the outcome as it relates to a fatality. The ideal ileostomy is one of the divided type in which the ileum with its mesentery is divided between clamps, one loop—the proximal—brought out at one level and the other loop at a separate level so that if later colectomy proves necessary it will be possible to excise the distal ileostomy together with its attached ascending and transverse colon and leave the proximal or permanent ileostomy undisturbed.

Operations involving colectomy after the establishment of an ileostomy when the ileostomy is of a loop type are extremely undecidable since one cannot with ease and safety cut off the attached distal segment of a loop colostomy and leave it just beneath the peritoneum. It adds considerably to the technical difficulties of colectomy following the establishment of an ileostomy if the ileostomy is of the loop type. It greatly simplifies this procedure if it is of the divided type, the ends being brought out at different levels.

It is of the utmost importance to realize the above point and to utilize the keenest judgment concerning when to do a loop colostomy and when to do a divided colostomy. If those patients with ulcerative colitis are in an advanced stage of intoxication at which stage in the past they have not infrequently been referred to a surgeon, any technical procedure as extensive as divided end ileostomy requiring manipulation of the ileum, ligation of the vessels within the mesentery, and division of that structure will be sufficiently extensive and will require sufficient manipulation of the infected ileum and colon so that a fatality from shock or peritonitis will be quite apt to occur. It is in this advanced and desperate type of ulcerative colitis when ileostomy is indicated that the simplest type of ileostomy should be done—that is, loop colostomy. In these desperate cases no attempt should be

made to visualize the colon Through a relatively small incision the terminal ileum should be found and picked up with the least degree of manipulation, a rod should be inserted underneath the mesentery, and the operation should be completed in the shortest possible time with the least amount of technical manipulation One can hardly overestimate the importance of the decision as to the type of ileostomy in the mortality of this disease

Another important thing in ileostomy, particularly in the end ileostomy in which a later colectomy may well be required, is that some form of suction apparatus be introduced into the ileum, particularly during the first week to ten days after the ileostomy has been established An excellent method has been devised by Dr Rolf Lum, a former Fellow in the clinic This is of great importance because ileal discharges, irritating the skin as they do, tend particularly to break the wound down If the liquid discharge of ileal contents can be controlled for seven to eight or nine days until the wound has healed, the skin can then be protected by the various materials that have been employed—bronze or aluminum paint or Fuller's earth The ileal contents may then, with relative impunity, be permitted to discharge upon the skin

Another important point to realize in connection with ileostomies is their tendency, due to infection and digestion about the wound, to loosen and to pull back into the abdomen This has happened in our experience more than once Likewise, there is the tendency for ileostomies to prolapse Because of these two facts, for some years we have fixed the mesentery of the ileum to the parietal peritoneum under the abdominal wall by several sutures (1) to overcome loosening and retraction of the established ileostomy and (2) to overcome the danger of its prolapse This is technically an extremely important point in the management of ileostomy

Following the establishment of an ileostomy there is frequently such striking improvement in the condition of these patients that they are hardly recognizable as the same individuals In a certain percentage of cases, however, because of stricturing and persistent infection and ulceration within the remaining colon, temperature reactions, together with discharges of blood and pus, occur One of the problems not unlike that of ileostomy in this disease then arises—that is, under such conditions when should removal of the remaining colon by partial or complete colectomy be

advised? Just as with ileostomy, one may defer this decision until such a time that it is so hazardous that when it is undertaken a fatal outcome will occur in too high a percentage of cases

We believe that when a patient who has had an active intractable ulcerative colitis with serious temperature reactions and loose discharges has had an ileostomy with relief and then has had a return of the activity of the process the question of colectomy should be seriously considered If relief from such a return of symptoms occurs and then recurs again, colectomy in our opinion becomes definitely advisable

In the performance of the colectomy in these cases the first portion of the operation will consist in the removal of the right and transverse colon up to the splenic flexure, the end of the remaining distant colon being brought out into the wound to rest upon the abdominal wall It has been the custom of some surgeons to close over this distal end and drop it back into the abdomen We have always felt that with the infection and stricturing so often present in the remaining bowel there is always the danger of such a closed end becoming opened and producing a peritonitis, an event which we know to have occurred in the hands of one of our friends interested in the surgical treatment of this disease We have found that there is little discomfort associated with the temporary implantation of this open distal end of the colon upon the abdominal wall, and certainly it is a definite safety factor in this operative procedure

In two to three months time through a long left rectus incision, the left colon and sigmoid are removed If the patient's condition permits, the patient is turned over after the abdomen has been closed, and the rectum is then removed These colectomies are done under nupercaine spinal anesthesia The mortality rate in the 48 colectomies (partial and complete) has been but 4 per cent

As we have discussed this disease, most of the questions such as the percentage of patients requiring surgery, the percentage of patients not requiring surgery, and the surgical mortality have been answered One of the most important questions, however, both to the physician who must advise these patients and to these patients themselves, is how does one manage with an ileostomy and is it possible to enjoy life satisfactorily with one?

The above questions should be answered

FIG 4a.

FIG 4b

FIGS 4a and 4b Typical ileostomy and type of bag worn with it

frankly By no stretch of the imagination may one say that ileostomy is as satisfactory an arrangement for the permanent discharge of the fecal stream through the abdominal wall as is colostomy. One must anticipate that, unlike colostomy in which by means of a constipating diet there will be no fecal discharge from the colostomy except with irrigation, with ileostomy a bag will need to be worn constantly. It will be necessary to empty the bag five to six times daily. A bag has been devised with a rubber flange about its neck which fits closely to the skin and with which patients remain quite dry and without objectionable odor about them (Fig 4).

One may also be reasonably sure in assuring patients with an ileostomy that with removal of their colon the management of their ileostomy will be made somewhat easier. There is something about the removal of the colon that causes the ileal discharge to be less fluid in character. Some time ago I suggested that this might well be due to the assumption of some fluid absorbing capacity on the part of the ileum after removal of the colon. One may certainly tell patients who are contemplating this surgical procedure that with an ileostomy they may undertake any activity they desire, that they may resume any reasonable occupation, and that the patients whom we now have with ileostomies are quite happy and contented individuals.

Conclusions

Our experiences with the operative and nonoperative treatment of ulcerative colitis are reported

The total mortality of the disease in our hands, together with the number requiring ileostomy and colectomy, partial and complete, is reported. The condition of the patients after colectomy is presented.

The indications for ileostomy are discussed, and the types of ileostomy and technical procedures to make them safer are recorded.

The indications for colectomy and the results from the patient's point of view after ileostomy are stated.

Discussion

Dr John H. Garlock, *New York City*—I have enjoyed hearing Dr. Lahey's paper and find that I am in accord with almost everything he has said. I believe everybody is agreed that the great majority of cases of ulcerative colitis constitute a medical problem and should never be considered for surgery. I am told by the gastroenterologists at Mt. Sinai Hospital that in the various departments at that institution there are seen throughout each year approximately 100 to 150 cases of ulcerative colitis. Yet, since 1937 when a more intensive study of the surgical therapy of this disease was initiated as a group problem, only 31 patients have been surgically treated.

May I emphasize again that the management of the cases that come to the surgeon is a cooperative problem involving the concerted efforts of the gastroenterologist, the medical staff, the x-ray department, the proctologist, and the surgeon. My associates and I have leaned heavily on the gastroenterology department headed by Drs. B. B. Crohn and A. Winkelstein.

As our experience has grown with this disease it has become more and more evident that certain criteria had to be established for the institution

of surgical treatment At the hospital we are fairly well agreed that the indications for surgery are the following (1) uncontrollable hemorrhage, (2) impending perforation, (3) acute fulminating colitis with marked toxemia, (4) chronic intractable colitis, and (5) segmental colitis.

The majority of the patients have had a preliminary ileostomy Our mortality with this procedure has been 11.7 per cent I believe the reduction in mortality in ileostomy depends essentially on the optimum time for the operation and the care with which the operative procedure is carried out. We have used a type of ileostomy similar to the one described by Dr Lahey without encountering one instance of prolapse of the proximal ileostomy stoma An important point in the technic of the operation is concerned with the determination of the surgeon never to visualize or palpate the diseased colon. The slightest touch of an instrument or a finger may produce a subsequent perforation

The experience of surgeons who are operating

for this disease throughout the country is insufficient at the present time to make any hard and fast rules concerning the removal of the rectum in every case of ulcerative colitis Inasmuch as the exact cause of this disease is as yet not known, and may be forthcoming at any time, we have felt that whenever possible, provided the general well-being of the patient will not be disturbed thereby, an attempt should be made to preserve the lower sigmoid and rectum for possible use at some future date in re-establishing intestinal continuity In the 31 cases already referred to, we have found it necessary to remove the rectum in only two cases because of extensive perirectal infection and perianal sinus formation We have under observation 2 or 3 cases in whom there is a progressive restoration of the rectal mucosa to normal

This entire problem is of great importance and will require continued concerted efforts of the gastroenterologist and surgeon before a solution is found.

TOO MANY APPENDICITIS DEATHS

Deaths from appendicitis in the United States increased from 7,371 in 1900 to over 18,000 in 1930 Although the number of deaths has fallen off since then, it is estimated that about 14,000 people died from this disease in 1939 In 1937, the last year for which reliable information is available, the United States had the second highest death rate from appendicitis in the world The disease strikes persons of both sexes, and at all ages, neither infants nor old people are spared.

Surely, any disease which causes so many deaths each year is a matter of vital public concern, remarks *Public Health Reports* Appendicitis cannot be prevented, but within certain definite limitations few deaths, if any, need result from this disease

MOTION PICTURE ON TUBERCULOSIS

Tuberculosis and two of its victims are the theme of *They Do Come Back*, a new sound motion picture produced by the National Tuberculosis Association, reports *Health News* This film was designed especially to visualize the relationship between rehabilitation and the rest of the tuberculosis program and to inform the public regarding the need and the nature of rehabilitation service.

The State Health Department has added *They Do Come Back* to its collection of circulating health motion picture films The running time is about seventeen minutes Prints in the 16-mm size may be borrowed, subject to the usual conditions, by applying to the Supervisor of Visual Instruction, State Department of Health, Albany, New York.

MARROW TRANSFUSIONS

The simple process of injecting healthy bone marrow (the soft material which fills the bone cavities and takes part in the building of blood) into that of the breast bone of patients with marrow deficiencies may lend itself to the solution of many problems of blood disorders, Drs Maurice Morrison and A. A. Samwick, of Brooklyn, suggest in the *J.A.M.A.*

Blood cells develop in the bone marrow and are discharged into the blood stream when mature Thus there is a direct relationship between disturbances of the marrow and of blood formation

GOVERNMENT MEDICINE AT WORK

I visited the State of New Mexico I went to Hot Springs I saw a hospital that cost \$2,500,000 accommodating 90 crippled children, built out of Government money Yet there was not a single orthopedic surgeon in the State of New Mexico to take care of those crippled children So they import an orthopedic surgeon two mornings a week from El Paso, Tex., on a salary larger than that paid to the Governor of New Mexico in order to take care of 90 children in a hospital in a town of three or four hundred people in the State of New Mexico That is Government medicine—Dr Morris Fishbein

Discussion

Dr John H. Garlock, *New York City*—I have enjoyed hearing Dr. Lahey's paper and find that I am in accord with almost everything he has said. I believe everybody is agreed that the great majority of cases of ulcerative colitis constitute a medical problem and should never be considered for surgery. I am told by the gastroenterologists at Mt. Sinai Hospital that in the various departments at that institution there are seen throughout each year approximately 100 to 150 cases of ulcerative colitis. Yet, since 1937 when a more intensive study of the surgical therapy of this disease was initiated as a group problem, only 31 patients have been surgically treated.

May I emphasize again that the management of the cases that come to the surgeon is a cooperative problem involving the concerted efforts of the gastroenterologist, the medical staff, the x-ray department, the proctologist, and the surgeon. My associates and I have leaned heavily on the gastroenterology department headed by Drs. B. B. Crohn and A. Winkelstein.

As our experience has grown with this disease it has become more and more evident that certain criteria had to be established for the institution

persistently open. A young girl had such a tumor in the mouth of the upper lobe of the right bronchus. In spite of a good pneumothorax it was found impossible to close the cavity. Removal of the tumor, however, and opening the bronchus allowed the cavity to contract.

Occasionally, a tuberculous ulcer or granuloma will be the site of hemorrhage. We have encountered 3 such cases in which the need of bronchoscopic treatment was urgent since the hemorrhage was not controlled by other measures. Few will deny then that occasions may arise when scar strictures, tumors, and hemorrhages from ulcerations may demand treatment.

On the other hand, there is no doubt that many tracheal or bronchial lesions will heal without direct local treatment. To illustrate this point let me cite a case that occurred in the service of my colleague, Dr. Alexander Ghiselin at the Seton Hospital.

A young woman, 28 years of age, was admitted to Bellevue Hospital on July 26, 1938, with a complaint of fatigue, productive cough, and cervical adenitis of four months' duration. An x-ray previously taken showed minimal apical involvement. Four months later she began with wheezing on the left side near the midline, both inspiratory and expiratory. Her sputum was more profuse, with slight dyspnea. The sputum taken in January was reported positive. She was admitted to the Seton Hospital on January 19, 1938. The patient seemed much sicker than the pulmonary lesion warranted. Her weight was 90 pounds, and she had a paroxysmal productive cough. Bronchoscopy performed on February 16, 1939, was as follows:

"There is a lesion beginning on the left wall of the trachea 2 cm. above the carina and extending around 25 per cent of the circumference. The entire left main bronchus is involved in a tuberculous bronchitis, continuous with the tracheal lesion. The tissue of the lesion is the hyperplastic type which is very friable and bleeds easily. Silver nitrate ten per cent applied."

Another bronchoscopy was performed February 28, 1939, with about the same findings. As the patient reacted badly to the bronchoscopic treatments they were abandoned. The patient went steadily downhill—profuse positive sputum, paroxysmal cough, temperature range 101 to 102 F daily. During June, 1939, clinical and x-ray evidence of total left bronchial obstruction developed, and this was followed by an effusion that was tapped on the left posteriorly, about 400 cc being removed each time. After this procedure the temperature suddenly dropped to normal, the patient started to gain weight, sputum decreased, and wheeze disappeared. The effusion was absorbed.

A bronchoscopy performed on November 30, 1939, revealed normal dry bronchial tree. No sign of scar or stricture to indicate that there was ever any endobronchial involvement. She continues to gain weight, her sputum is now negative, her temperature is normal, and the cervical adenitis has subsided.

To summarize, this represents a case with extensive pulmonary and tracheobronchial lesions, bronchoscopically examined twice. After this, the patient was extremely ill for a long time but finally became better. She was examined with a bronchoscope again after the improvement, and complete healing without traces of disease of the tracheobronchial tree was found. The two lesions had improved together. Certainly if this case had been treated bronchoscopically and such result had come about, the temptation would have been to claim the good results had been produced by the bronchoscopy.

A similar case occurred in my own experience.

A woman, about 50 years of age, was quite sick with tuberculosis and complained a great deal of wheezing and shortness of breath. She had a rather extensive pulmonary tuberculosis. The report on the bronchoscopy was as follows:

"Larynx was negative. Beginning below the vocal cords there was extensive ulceration of the tracheal wall, very shallow and superficial, seemingly involving only the mucous membrane. Further down, however, there were masses of granulation tissue which obstructed the lumen of the trachea. There had also been some healing and scar tissue formation. Just above the bifurcation the lumen was so narrow that the tube could not be passed to the bifurcation, hence no observation on the condition of the main bronchi could be made. Silver nitrate was applied to the granulation tissue."

Two weeks later we had this report from her doctor: "She is a very miserable person, complains of coughing constantly. She has a constant 'sick stomach,' eats very little, temperature ranges from normal to 102, often high in the morning and normal at night." This patient appeared to be so sick that hope was almost given up, yet she improved so that we were able to examine her with a bronchoscope again on April 29, 1938, just five months later. I was able then to report on the bronchoscopy as follows:

"The tracheal ulceration appeared to be healed although the mucous membrane was still extremely red. There was still extensive ulceration in the right bronchus. Used vapor mercury lamp."

After this bronchoscopy the patient improved so that another bronchoscopy in May, 1938, was done. The mucous membrane of the

RESULTS OF TREATMENT OF TUBERCULOSIS IN THE TRACHEA AND BRONCHI

JOHN D. KERNAN, M.D., and A. J. CRACOVANER, M.D., New York City

IN CONSIDERING the results of treatment of tuberculosis in the trachea and bronchi, let it be understood that I am speaking from the point of view of the bronchoscopist and that the treatment I am dealing with is treatment applied through the bronchoscope. I think it is generally agreed that for diagnostic purposes in pulmonary tuberculosis bronchoscopy is extremely useful. This procedure quickly and accurately clears up questions as to the cause of persistent positive sputum, wheezes, hemorrhage, shortness of breath, and other symptoms that are obscure to the ordinary methods of examination.

Once the diagnosis of tracheal or bronchial tuberculosis is made, then the question of treatment arises. The first point to consider is, should there be any bronchoscopic treatment? There are those who consider that the ordinary treatment of pulmonary tuberculosis carried out by the medical man, or by the chest surgeon when necessary, is quite sufficient and that if the pulmonary lesion is healed the bronchial lesion will heal spontaneously at the same time.

The question, however, is not so simple as that. In the course of pulmonary tuberculosis symptoms will arise which call for immediate relief. Consider, for instance, the circumstances when a bronchus is obstructed by scar tissue or a tuberculous granuloma. The effects of any obstruction on the bronchi and lung beyond are disastrous; the lung will collapse, and sooner or later infection will ensue and abscess or bronchiectasis will follow. It is, therefore, sometimes necessary to make an attempt to stretch a scar or to remove a tumor for purposes of drainage. Let me illustrate by a case.

This woman had been treated a long time for tuberculosis and had what appeared to be a successful pneumothorax. Her symptoms, however, persisted—cough, sputum, afternoon fever, and the like. Bronchoscopy showed a contracted left main bronchus with granulation tissue obstructing the remaining lumen. This granulation tissue was reduced by silver nitrate, and the lumen was dilated sufficiently to admit an aspirating tube. A considerable quantity of pus was removed by

aspiration, and the same procedure was carried out several times. The abscess soon dried up, and the woman became symptom-free. She now has a greatly contracted main bronchus, the pneumothorax, no sputum, no cough, and no fever.

The results of stretching scar structures are not always so successful. We have had several cases in which the suppuration has tended to persist and in which only continued treatment keeps the lumen open enough for drainage. It is our custom to dilate these cases whenever symptoms of obstruction arise as shown by pain in the chest, rise of temperature, and limitation of sputum. The method first used by us for dilatation was the use of the glove-stretcher dilator. More recently we have been using a copper bougie through which is passed a positive galvanic current. This has seemed to result in permanent softening of the scar tissue.

Occasionally, contracted bronchi will close completely. This does not always result so disastrously as one would expect. One of our most successful cases was a woman who had an extensive ulceration in the lower end of the trachea and left main bronchus. Several bronchoscopic applications of silver nitrate resulted in complete healing of the ulceration and complete closure of the left main bronchus. In spite of the fact that one would have expected the complete cessation of drainage to make the patient very sick, on the contrary, all her symptoms cleared up at that time and have not recurred. This suggests that in certain cases where it is possible to get a fairly dry lung it might be good treatment to close purposely the bronchus and so suspend the function of the particular lung in question. The late Dr. Pol Caryllos showed, by experimental work on dogs, that large cavities could be closed by occluding the bronchus leading to them.

Tuberculous tumors should be removed preferably by diathermy coagulation or by silver nitrate. It is not advantageous to use forceps, as this procedure causes some bleeding and, if the blood gets in other parts of the lung, may result in the spread of the disease. Sometimes a tumor in the mouth of a bronchus will have a ball-valve effect and trap air in the lung in such a way that cavities stay

persistently open. A young girl had such a tumor in the mouth of the upper lobe of the right bronchus. In spite of a good pneumothorax it was found impossible to close the cavity. Removal of the tumor, however, and opening the bronchus allowed the cavity to contract.

Occasionally, a tuberculous ulcer or granuloma will be the site of hemorrhage. We have encountered 3 such cases in which the need of bronchoscopic treatment was urgent since the hemorrhage was not controlled by other measures. Few will deny then that occasions may arise when scar strictures, tumors, and hemorrhages from ulcerations may demand treatment.

On the other hand, there is no doubt that many tracheal or bronchial lesions will heal without direct local treatment. To illustrate this point let me cite a case that occurred in the service of my colleague, Dr. Alexander Ghiselin at the Seton Hospital.

A young woman, 28 years of age, was admitted to Bellevue Hospital on July 26, 1938, with a complaint of fatigue, productive cough, and cervical adenitis of four months' duration. An x-ray previously taken showed minimal apical involvement. Four months later she began with wheezing on the left side near the midline, both inspiratory and expiratory. Her sputum was more profuse, with slight dyspnea. The sputum taken in January was reported positive. She was admitted to the Seton Hospital on January 19, 1939. The patient seemed much sicker than the pulmonary lesion warranted. Her weight was 90 pounds, and she had a paroxysmal productive cough. Bronchoscopy performed on February 16, 1939, was as follows:

"There is a lesion beginning on the left wall of the trachea 2 cm. above the carina and extending around 25 per cent of the circumference. The entire left main bronchus is involved in a tuberculous bronchitis, continuous with the tracheal lesion. The tissue of the lesion is the hyperplastic type which is very friable and bleeds easily. Silver nitrate ten per cent applied."

Another bronchoscopy was performed February 28, 1939, with about the same findings. As the patient reacted badly to the bronchoscopic treatments they were abandoned. The patient went steadily downhill—profuse positive sputum, paroxysmal cough, temperature range 101 to 102 F daily. During June, 1939, clinical and x-ray evidence of total left bronchial obstruction developed, and this was followed by an effusion that was tapped on the left posteriorly, about 400 cc being removed each time. After this procedure the temperature suddenly dropped to normal, the patient started to gain weight, sputum decreased, and wheeze disappeared. The effusion was absorbed.

A bronchoscopy performed on November 30, 1939, revealed normal dry bronchial tree. No sign of scar or stricture to indicate that there was ever any endobronchial involvement. She continues to gain weight, her sputum is now negative, her temperature is normal, and the cervical adenitis has subsided.

To summarize, this represents a case with extensive pulmonary and tracheobronchial lesions, bronchoscopically examined twice. After this, the patient was extremely ill for a long time but finally became better. She was examined with a bronchoscope again after the improvement, and complete healing without traces of disease of the tracheobronchial tree was found. The two lesions had improved together. Certainly if this case had been treated bronchoscopically and such result had come about, the temptation would have been to claim the good results had been produced by the bronchoscopy.

A similar case occurred in my own experience.

A woman, about 50 years of age, was quite sick with tuberculosis and complained a great deal of wheezing and shortness of breath. She had a rather extensive pulmonary tuberculosis. The report on the bronchoscopy was as follows:

"Larynx was negative. Beginning below the vocal cords there was extensive ulceration of the tracheal wall, very shallow and superficial, seemingly involving only the mucous membrane. Further down, however, there were masses of granulation tissue which obstructed the lumen of the trachea. There had also been some healing and scar tissue formation. Just above the bifurcation the lumen was so narrow that the tube could not be passed to the bifurcation, hence no observation on the condition of the main bronchi could be made. Silver nitrate was applied to the granulation tissue."

Two weeks later we had this report from her doctor: "She is a very miserable person, complains of coughing constantly. She has a constant 'sick stomach,' eats very little, temperature ranges from normal to 102, often high in the morning and normal at night." This patient appeared to be so sick that hope was almost given up, yet she improved so that we were able to examine her with a bronchoscope again on April 29, 1938, just five months later. I was able then to report on the bronchoscopy as follows:

"The tracheal ulceration appeared to be healed although the mucous membrane was still extremely red. There was still extensive ulceration in the right bronchus. Used vapor mercury lamp."

After this bronchoscopy the patient improved so that another bronchoscopy in May, 1938, was done. The mucous membrane of the

trachea and the left main bronchus was normal in appearance. Any trace of the former ulceration and congestion no longer existed. The right main bronchus was negative to below the middle lobe bronchus. At this point there was a stricture so that the lumen was about $\frac{1}{4}$ inch across. The lips of this stricture were congested, and beyond it there was evidently ulceration, as the suction tube when passed started up a little bleeding.

This case is one of very extensive tracheal tuberculosis which healed with minimum treatment. In view of the case previously reported and in view of the fact that she had only two treatments, I hardly venture to maintain that the healing was the result of the bronchoscopies. Yet note this: Only the area reached at the first bronchoscopy healed after that bronchoscopy. After the second bronchoscopy the right bronchus healed.

These 2 cases, I feel, present the case of those men who maintain that it is not necessary to actively treat tracheobronchial tuberculosis through bronchoscopy but that one should content oneself with an occasional observation. This is very different from a weekly or fortnightly bronchoscopy.

There is much to be said, however, in favor of treatment. Consider what happens to the untreated cases. One patient had tracheobronchial tuberculosis and was never treated except by general measures. A very extensive scarring and contraction was evident. The disease had advanced to complete destruction of the bronchus, and under such a condition, of course, the lung beyond will be completely destroyed. It certainly would be worthwhile to avoid such a result if possible, and I am quite sure it could be contended that early and persistent treatment will heal many lesions before they advance to such a stage of destruction.

The result of treatment will, of course, depend much on the stage at which treatment has started and on the nature of the lesion. Beyond any doubt, shallow ulcerations and localized masses of granulation tissue involving for the most part the mucous membrane are more or less easily controlled. If, however, the tuberculosis has started deep in the wall of the bronchus and has involved the whole thickness of the wall with destruction of the cartilage, treatment will naturally be much less effective. Small shallow ulcers and localized masses of granulation tissue heal promptly. Tight strictures and deep extensive ulcerations require prolonged treatment and many bronchoscopies.

The following is the report on 56 cases. We have had a number of other cases, but treatment and observation were not carried on long enough for any conclusions to be drawn. The results here reported pertain only to the bronchial lesions. Some of the cases may have developed further parenchymal lesions or even may have died from the tuberculosis. We report only on the effects of treatment or the tracheobronchial lesions.

Lesions Found on Bronchoscopy

Ulceration or Granulation Tissue—50 Cases.

The ulcers varied in size and depth, some merely small patches and others including the whole circumference of the trachea or bronchus. It must be remembered that only the upper end of an ulcer can be seen through the bronchoscope. It is difficult to tell how far down a bronchus the lesion reaches. In 7 of the cases with ulcers some healing had already taken place so that fibrous strictures were also present. The granulation tissue varied in amount from small elevated masses to tumors so large as to be obstructive. It may be asked here how we knew that they were tuberculous ulcers and not merely simple ulcers. For the most part it was assumed that an ulcer on the side of the pulmonary lesion when the sputum was positive was tuberculous. This may not be a highly scientific attitude, but it was not considered safe to confirm the diagnosis by taking biopsies. In a few cases the diagnosis was confirmed by stained smears.

Fibrous Strictures—4 Cases.—We considered that these indicated the previous presence of an ulceration that had healed.

Swollen Mucous Membrane—2 Cases.—These cases had much the same symptoms as those obstructed by granulation tissue or fibrous stricture, and yet only an intensely red, swollen, mucous membrane could be seen.

Symptoms Which Called for Bronchoscopy

Wheeze.—Thirty-six cases had as their main symptom wheeze, sometimes loud enough to be heard at a distance from the patient. At times this was accompanied by a persistent cough. In 1 case the adventitious sound took the form of a fluttering on both inspiration and expiration. This proved to be caused by a pedunculated mass of granulation tissue which moved up and down on respiration.

Positive Sputum Persisting—13 Cases.—In these cases the pulmonary lesion was considered to be well controlled or even healed, and yet the sputum continued to be positive. The discovery of a bronchial lesion was considered to be sufficient explanation. At times this lesion was found on the opposite side from the pulmonary. As a rule the sputum became negative when the ulcers healed.

Hemorrhage—Three cases were examined by a bronchoscope because of hemorrhage. Ulcerations were found. Treatment of the ulcers controlled this symptom. In 1 case bleeding recurred after eighteen months. Bronchoscopy showed that the bronchial lesion had recurred.

Severe Dyspnea—3 Cases—These were cases of extensive tracheal ulceration with either masses of granulation tissue or scar tissue causing the obstruction. They were naturally difficult cases to handle. One of them showed no tendency to improve and died from spread of the disease in the lungs. A second of these cases healed with almost no trace of the disease in the trachea but later died of pulmonary disease. The third had a healed tracheal lesion but with extensive scar formation. This calls for monthly stretching with bougies. This woman was at first examined with a bronchoscope every week, the tube being passed through the ulcerated trachea. In spite of this weekly trauma, the ulcerations have healed.

Persistent Cavity—1 Case—This girl was being treated for a pulmonary lesion on the right side. In spite of an excellent pneumothorax the cavity in her lung could not be collapsed. When she was examined with a bronchoscope, a small tumor was found in the mouth of the upper lobe of the right bronchus, which was obstructed by the ball-valve action of the tumor. Removal of the tumor aided in the reduction of the size of the cavity.

Methods of Treatment

Our first treatment was diathermy coagulation. We used it on only 3 cases. Two responded very well as far as the disappearance of the lesion was concerned, but there was formation of considerable scar tissue. In the third case, which appeared to be improving, a fatal hemorrhage occurred shortly after treatment. The lesion was extensive in this case. The improvement noted was only illusory as the lesion extended far beyond the reach of treatment, both in length and depth. Coagulation was given up.

Silver Nitrate 10 Per Cent.—Twenty-one cases were treated in this manner. It proved to be efficient and it is certainly simple. Silver nitrate has no such healing effect on tuberculous tissue elsewhere—for instance, in the larynx. One may suspect that perhaps some of the ulcerations that healed so promptly were simple granulation tissue, not tuberculous. The demonstration by several workers that strong silver nitrate can close a bronchus made us fear that this might occur in our cases, so we use silver nitrate with great caution, not stronger than 10 per cent.

Mercury Vapor Lamp—14 Cases—This is used every week or two through the bronchoscope. It appears to be efficient and produces a minimum of scar tissue. Some of the cases in which silver nitrate failed, healed under treatment with the mercury vapor lamp. A

comparison of the number of treatments needed with silver nitrate and the lamp shows that those treated with the first needed two to six treatments and those with the latter needed four to fourteen treatments, so that those treated with the quartz light took longer to heal. Treatment of an ulcer in some cases produced a stricture that, in turn, had to be dilated by ionization. It is suggested that the mercury vapor lamp can be applied for a much longer time than hitherto, also, by using a flexible shaft it could be inserted without bronchoscopy once the distance of the lesion from the teeth had been ascertained. This would considerably simplify treatment. Silver nitrate, of course, could only be applied through the bronchoscope.

To compare further the use of the mercury vapor lamp and silver nitrate it may be noted that, of 14 cases treated at first by the lamp alone, 11 healed without other treatment. Of 21 cases treated at first by silver nitrate alone, only 11 healed without other treatment—namely the lamp. Of the 11 cases in which both were used, 8 got well.

Length of Time—Treatment lasted from two weeks to six months, i.e., from the first treatment to complete healing.

Results

Twenty cases were completely healed, 6 cases, completely healed with slight narrowing of the bronchus, 5 cases, completely healed with stricture of the bronchus, 3 of these strictures were treated by ionization successfully so as to give an adequate lumen and 1 of these strictures did not yield to treatment and remains stenosed, but the patient is symptom-free, 2 cases, completely healed with complete occlusion of a bronchus, and 2 cases of stricture of the bronchus treated with ionization were dilated to such an extent so as to produce an adequate lumen (Caruso and Inglin).

Therefore, 35 cases may be considered cured as far as their endobronchial lesion is concerned. Nine cases were complete failures. Three cases were improved, but the improvement was not adequate and treatment was suspended. Eight cases were improved at the time of their last treatment but for some reason patients did not return for further observation and care. One case is still under treatment. This completes the 56 cases.

In this series 4 cases had recurrence of the ulceration and by further treatment were healed again, indicating the need for continued observation. Three cases had recurrence but did not heal when further treatment was instituted. Three attempts were made to

occlude the bronchus permanently by treatment with strong silver nitrate, cautery, and cauterization with ionization—these were failures

In this series there were 2 cases that developed a spread of the infection following bronchoscopy. It is difficult to say, however, whether the bronchoscopy was the cause of the spread or not. One case eventually became entirely healed. The other died shortly afterward of miliary tuberculosis. The autopsy in this case showed the bronchus to be healed.

One case expired following bronchoscopy when she developed a profuse hemorrhage on cauterization of an ulcerative lesion.

Bronchoscopy is useful for diagnosis. Certain cases urgently call for bronchoscopy for treatment purposes. Many other cases are healed more quickly and with less damage by bronchoscopic treatment. The use of the mercury vapor lamp will probably prove most efficient.

103 East 78th Street

Discussion

Dr. Edward N. Packard, *Saranac Lake, New York*—The brief time allotted to me precludes a thorough discussion of the various points raised by Dr. Kernan on the diagnosis and treatment of tuberculous tracheobronchitis. I would like, however, to emphasize the growing importance of the place of the bronchoscopist in the treatment of pulmonary tuberculosis. Some ten or twelve years ago the observation was made that atelectasis of the lung, in whole or in part, could and did take place in a fair number of patients with tuberculosis. Some of these patients later came to autopsy, and it was found that what initiated the collapse of the air cells was an occlusion of the main stem bronchus. In the cases that I saw, the lumen of the bronchus was blocked by a collar of dense fibrous tissue surrounding and involving the bronchial wall. This was tuberculous in origin. Dr. Kernan mentioned in his paper that the end results of such an occlusion may be good or they may be bad. Cavities have closed as a result of this blocking process, and the diseased lung eventually has become a fibrous mass—the so-called *carinated lung*. On the other hand, the results of such bronchial occlusion may be disastrous. Pyogenic material locked up within the lung may take on all the characteristics of an acute pulmonary abscess. One of the important roles that the bronchoscopist is called upon to perform is to attempt, by whatever means he has at hand, to forestall these dire consequences. Dr. Kernan has outlined for us the various procedures that he has employed.

If a bronchus can become occluded by tuberculous changes within or around its lumen, then there should be some means of recognizing

beginning or partial stenosis. It is now well established that the so-called asthma of which tuberculous patients sometimes complain is, in the great majority of instances, due to bronchial obstruction and not to an allergic state. Again the localized and persistent wheeze heard during both phases of respiration is almost pathognomonic of bronchial obstruction. The bronchoscopist can visualize the offending disorder, and many times he can cure, or at least give, relief.

The more frequent use of the bronchoscope in tuberculous patients has revealed unsuspected ulceration of the mucosa of various parts of the bronchial tree. These ulcers are as difficult to heal as tuberculous ulcers in other organs or tissues, and one might argue, as Dr. Kernan points out, that when healing takes place after a few bronchoscopic treatments the process may be due to nontuberculous chronic bronchitis. However, the removal of tissue for microscopic study is hardly justified for fear of creating fresh ulceration.

I would like to say a further word on the importance of visualizing the major bronchi before collapse measures for tuberculosis are carried out. This applies particularly to artificial pneumothorax, and thoracoplastic operations. In a patient who is dyspneic, who wheezes, or who has difficulty in raising sputum, much harm may be done by collapsing the lung, particularly if extensive, ulcerative, tracheo-bronchial tuberculosis is present. Here we are entirely dependent upon the bronchoscopist, and the future course of the patient for good or for bad may rest upon what he sees or upon what he is able to accomplish. If the symptoms are due to partial stenosis but are of the smooth membrane type, collapse measures are not necessarily contraindicated.

What I have thus briefly touched upon, without commenting upon the efficiency of the various procedures used to attempt to heal ulcers or relieve strictures, gives a broad point of view of the role that bronchoscopy plays in the present-day treatment of pulmonary tuberculosis.

Dr. J. Maxwell Chamberlain, *Oneonta, New York*—We are all aware of the debate in regard to the bronchoscopic treatment of endobronchial tuberculosis. This is due to the fact that we are unable to establish an absolute control. In other words, no one is able to estimate accurately the effect of improvement in the pulmonary lesion on the endobronchial disease, and, even if this could be roughly determined, we should need identical bilateral lesions in a single patient. Then one side could be treated and the other side reserved as a control. However, we have learned much in the last ten years about the treatment of endobronchial tuberculosis, and once the term "cure" is defined we are practically all in agreement.

If one is overenthusiastic about the broncho-

scopic therapy of endobronchial tuberculosis, a "cure" may mean that the operator can no longer see the ulcer or granulation tissue that characterized the acute phase of the disease. We have all treated acute disease in the stem bronchus and watched it disappear around the corner, as it were, of the upper lobe of the bronchus. To use the term loosely, we have then "cured" the endobronchial disease, at least all one can see. Sometimes the upper lobe orifice is never seen because the ulcer is replaced by a fibrostenotic lesion which forbids the passage of the bronchoscope. Yet few of us would consider this in itself a "cure." On the other hand, we frequently examine a patient with a bronchoscope for the first time and find a fibrostenotic lesion of the stem bronchus. This is often sighted as evidence of a "spontaneous cure," and the endobronchial disease is said to be "self-limited." In one hospital, I recently examined 10 patients in succession with a bronchoscope for the first time. Two had endobronchial disease in the acute phase, and 8 had a fibrostenotic lesion. All 10 had a positive sputum. We are hardly justified in speaking of such results as endobronchial "cures." Fibrostenosis is not a "cure" in itself. It is a catastrophe which should not be allowed to happen until the pulmonary lesion is controlled. For the acute bronchial lesion to proceed to the fibrostenotic stage in the presence of active pulmonary disease is proof of the greater healing potentialities (in general) of the bronchus in comparison with that of the lung. This unfortunate occurrence is contrary to good practice. Bronchial lesions should not get well in spite of the pulmonary lesion. Adequate therapy directed at the pulmonary lesion should be so established that the two phases of the same disease get well simultaneously. The best

results and the real "cures" will be attained when the bronchoscopist and phthisiologist work hand in hand toward the mutual benefit of the patient.

Endobronchial tuberculosis in many cases responds in a most dramatic way. Dr Kernan's results are so good that I am sure he will agree with me that it is unusual for patients with acute disease to show no improvement after one or two bronchoscopic treatments (20 per cent silver nitrate). When such resistance is encountered I immediately suspect that the therapy directed at the pulmonary lesion is inadequate and should be changed. This should not be considered an admission that bronchoscopic therapy is valueless. It is only valueless in this case at this moment. I say "at this moment" because Dr Kernan has reported cases responding to the mercury vapor lamp which failed under silver nitrate. I should expect that improvement in the pulmonary lesion occurred simultaneously, perhaps due to a change in the adopted therapy. Though occasionally no improvement occurs as a result of treatment, much needed information is obtained. Each failure is a warning signal or index to the status of the pulmonary lesion. If the patient is on bed rest, collapse therapy may be indicated immediately. If an ineffective type of collapse therapy is in process, it should be converted into an effective one. The bronchoscopist may be, therefore, the first to realize the slight imbalance in favor of the disease, and it seems to me that the "bronchoscopic eye" and its "therapeutic test" is no less important in one's clinical evaluation of the patient than the temperature sheet or the weight chart. All patients with endobronchial disease in the acute phase should be given the advantages of bronchoscopic evaluation and treatment.

A DOCTOR'S REVENGE

There is a story about a French poodle of which James Abbott McNeil Whistler, the artist, was extravagantly fond, relates the *Philadelphia Evening Bulletin*.

This poodle was seized with an affection of the throat, and Whistler had the audacity to send for the great throat specialist, Sir Morell Mackenzie. The latter, when he discovered that he had been called to treat a dog, didn't like it much, but he said nothing. He prescribed, pocketed a big fee, and drove away.

The next day Dr Mackenzie sent post-haste for Whistler, who, thinking he was summoned on some matter connected with his beloved dog, dropped his work and rushed like the wind to the Mackenzie home. On his arrival Sir Morell said gravely

"How do you do, Mr Whistler? I wanted to see you about having my front door painted!"

A NEW DIVISION OF CHEMOTHERAPY

To facilitate research regarding new sulfanilamide products and new synthetic drugs with antimalarial properties to make the United States independent of the Dutch East Indies quinine supply and in order to extend work relating to opium and morphine derivatives and various studies relating to aging and nutrition, a new division has been set up in the National Institute of Health of the United States Public Health Service, Dr L. R. Thompson, director of the Institute, announces. The new unit will be known as the Division of Chemotherapy and will be headed by Surgeon W. H. Sebrell. National defense demands relating to synthetic drugs that may be needed to supplement present supplies of opiates and quinine have prompted this measure. Nutrition studies now being made are centering around the vitamin B complex.

THE CLINICAL COURSE IN VENTRICULAR ANEURYSM

HARRY GROSS, M D , and J B SCHWEDDL, M D , New York City

THE presence of ventricular aneurysm is frequently suspected on clinical grounds. In a previous paper¹ we summarized the findings of a correlative study of the x-ray and necropsy findings in 81 cases of ventricular aneurysm. All were associated with myocardial infarction due to coronary artery disease. Our purpose in this paper is, first, to review the clinical data in 43 cases of ventricular aneurysm, second, to compare these data with the usual findings in arteriosclerotic and hypertensive heart disease, unassociated with ventricular aneurysm, and third, to add additional diagnostic criteria, if possible.

All the cases were observed clinically over a period of years and confirmed by necropsy. The pertinent facts are summarized below.

There were 6 women and 37 men. The ages of the women ranged from 65 to 79, the ages of the men from 41 to 75. Two were under 50, 15 were between 50 and 60, 17 were between 61 and 70, and 2 were over 70. The preponderant occurrence of ventricular aneurysm is in the sixties. It is interesting to note that despite the fact that hypertension is more common in women and that it hastens the tempo of arteriosclerosis, myomalacia cordis, which occurs most commonly in association with hypertension, is, nevertheless, more severe and runs its course sooner in men. It is, however, well known that men are more frequently subject to coronary disease and myocardial infarction than women.

The duration of symptoms in the known cases ranged from six months to nine years up to six months, 2, six to twelve months, 4, one to one and one-half years, 5, one and one-half to two years, 4, two to three years, 6, three to five years, 10, five or more years, 6, duration unknown, 6, total cases, 43.

The onset with angina occurred in 25 instances. No attempt was made to determine the association of angina pectoris with cardiac infarction, since the electrocardiogram of transitory attacks may simulate that of cardiac infarction and also since cardiac infarction may occur without cardiographic changes or pain.² Anginal pain lasted from six months to nine years. In 13 cases the anginal onset and failure coincided. The occurrence of

failure with angina makes it likely that cardiac infarction took place at such a time.

In 6 cases the onset was with dyspnea, in 4 cases paroxysmal dyspnea was the dominant symptom at the start. One had pulmonary edema and 3 had congestive failure at the onset. In 4 others in which there were no symptoms referable to the heart, the diagnosis of ventricular aneurysm was made only at the postmortem examination. Three of these were associated with malignancies and 1 with tuberculosis.

Paroxysmal nocturnal dyspnea and pulmonary edema were regarded as congestive failure and were present in 16 patients. These symptoms lasted from three months to six years. In 5 cases paroxysmal dyspnea or pulmonary edema persistently recurred throughout the entire course, lasting six years, three years, two years, one year, and eight months, respectively. With but 1 exception there was objective congestive failure in every case of paroxysmal dyspnea or pulmonary edema.

Congestive failure lasted from six months to seven years. In 5 cases congestive failure lasted less than six months, 5, from six to twelve months, 3, from one to one and one-half years, 4, from one and one-half to two years, 8, from two to three years, 5, from three to five years, and 3, for more than five years.

Hypertension was known or could be assumed from the heart weight in 35 of the 43 cases. In 4 cases a heart weight of over 400 but less than 500 Gm was not enough to establish or definitely exclude pre-existing hypertension. The association of coronary artery disease with hypertension and the role of high blood pressure in cardiac enlargement are well established. In the absence of valvular deficiency or renal disease, cardiac enlargement may be attributed to hypertension,³ with few exceptions.

Electrocardiograms were available in 29 cases, with results shown in Table 1.

A correlation between the electrocardiographic findings and the site of myocardial infarction was possible, but no correlation existed between the electrocardiographic findings and the anatomic site of ventricular aneurysm. In 5 instances a fall in voltage was observed, in 5 others it was already pres-

From the Medical Service of Dr. L. Lichtwitz and the Radiological Service of Dr. A. J. Bendick, Montefiore Hospital.

ent on admission. Such drop in voltage, as well as the superimposition of abnormal rhythms, is less characteristic of ventricular aneurysm than of heart muscle damage incidental to the underlying etiology of the heart disease.

The single positive finding is the comparative frequency of right axis deviation.⁴ Three developed a shift from left axis to right axis deviation. Three already had a right axis deviation when first seen. This comparative frequency (6 out of 29 cases) of right axis deviation may possibly be due to the enlargement of the right ventricle as a result of congestive heart failure. Aside from the relatively frequent occurrence (21 per cent) of right axis deviation, the electrocardiographic findings were those commonly encountered in hypertensive heart disease or those associated with extensive myocardial damage. Therefore, it is evident that no typical electrocardiographic evidence exists for ventricular aneurysm.

The overwhelming majority of the cases examined had greatly enlarged hearts, and the occurrence of hearts weighing 600 to 900 Gm. was very common. One heart weighed 1,100 Gm. Twelve weighed 450 Gm. or less, eight, 400 Gm. or less, the average heart weight was 555 Gm. No correlation was found between the occurrence of aneurysm and the heart weight. The bulge did not appear to contribute to the increase in heart weight.

Discussion

A disparity characterized by a large apical impulse and disproportionately poor heart sounds is a clinical sign of ventricular aneurysm. The diagnosis was suspected on this basis several times. On a number of occasions when the diagnosis was made on the basis of this disparity, ventricular aneurysm was not found. The value of this sign was therefore of limited import.

The sites of ventricular aneurysm have been noted in Table 2. No correlation was found between the site of the vascular lesion and the location of myocardial infarcts, nor with the actual site of ventricular aneurysm. Vascular disease ranged from sclerosis of one major coronary artery to occlusion of every major coronary artery. In 1 unusual case, myocardial infarction and ventricular aneurysm occurred in the absence of coronary artery closure or even marked sclerosis.

In each of 4 instances there were 2 aneurysms. In 2, a high posterior aneurysm of the left ventricle was found along with an aneu-

rysm in the diaphragmatic portion of the right ventricle. Two others had both aneurysms in the left ventricle involving the upper portion of the posterior surface and the lower portion of the lateral wall.

In 13, the size of the aneurysm was known. The smallest measured 7 sq. cm. (diameter 3 cm.). The largest was 7 by 15 cm. Both the largest and the smallest aneurysms were in hearts from hypertensive cases. No correlation was found between increased heart weight and the size or site of ventricular aneurysm.

The mechanism of bulge formation is known. A bulge is a local evagination of a segment of the ventricular wall. Myocardial infarction when healed results in fibrous replacement and thinning of the ventricular wall. Before the fibrotic replacement is extensive, rupture of the ventricle may occur. Our cases represent the healed stages in which the bulge is formed by a fibrous scar replacing this portion of heart muscle. No instances of rupture occurred in our patients, and we know of none in the literature. The resilience of the resulting scar depends upon many factors. These are the size of the area infarcted, the site of infarction, the presence or absence of intramural thrombus, calcification, pericardial adhesions, and the supportive effect of the surrounding structures. It is obvious that an area of myocardial infarction must be at least a certain size before its surrounding structure will allow it to bulge. Large areas of myocardial infarction are therefore more prone to bulge formation than small ones.

An important factor in bulge formation is

muscular strain or work Sutton and Davis⁵ showed experimentally that soon after coronary occlusion animals forced to work developed ventricular aneurysm, whereas the hearts of animals spared such effort healed without the development of ventricular aneurysms

It is possible that in humans increased intraventricular tension associated with effort plays a role in bulge formation. Even normal tension may conceivably be excessive, especially if the area is large and the wall thin. Added tension incidental to effort during the early phases of healing after

myocardial infarction must be borne in mind as an additional contributory factor to bulge formation

The difference between intraventricular pressure within the right and left ventricles probably accounts for the more frequent development of aneurysm in the left ventricle. The support of the diaphragm probably accounts for the very infrequent involvement of the diaphragmatic portion of the right ventricle. While ventricular aneurysms may increase the size of the heart, such enlargement in our experience is not generalized but localized. It is our opinion that generalized car-

diac enlargement not attributable to other causes is due to hypertension or antecedent hypertension

The radiographic findings have been discussed in a previous paper.¹ In the examination, fluoroscopy is of more value than the use of films. The most important single criterion is the presence of a bulge. This may occur anywhere in the contour of the left ventricle, be it lateral, anterior, posterior, high, or low. At times, deep inspiration will reveal a bulge below the level of the dome of the diaphragm. A bulge in the cardiophrenic region is very difficult to recognize but may be identified by careful inspection during deep inspiration. A lateral bulge will produce few difficulties if the left ventricle is correctly identified by carefully noting the point of junction of opposite pulsations. A bulge of the posterior wall is somewhat more difficult to identify within the structures of the posterior mediastinum. Careful examination in such cases may reveal a bulge breaking the contour of the posterior surface so that a correct diagnosis may be made.

A definite incisura or angulation between the site of the bulge and the uninvolved portion of the ventricle is observed occasionally. Increase in density and pericardial adhesions frequently serve to identify the site of an aneurysm. Increase in density is attributed to intraventricular thrombus, occasionally with added calcific deposition. An important group virtually impossible to diagnose is that in which so massive a portion of the left ventricle is involved that there is enlargement of the entire lateral wall simulating other types of enlargement of the left ventricle.

Within the past few years considerable significance has been attached to the pulsations of the ventricular wall in cardiac infarction and in ventricular aneurysm. Some stress has been placed upon the contrapulsile nature of the pulsations, especially in ventricular aneurysm. Our findings and those of others, whose reports we summarized in a previous paper, do not lead to an identical conclusion. The pulsations may be strong or weak, synchronous or asynchronous, systolic or contrapulsile. However, in the majority of instances, asynchronicity with contrapulsile pulsations is present

In all but 1 patient, chronic congestive failure lasted from six months to nine years. In addition to clear evidence of water retention, we regarded paroxysmal dyspnea and pulmonary edema as evidences of congestive heart failure. Using these criteria, the vast majority of the cases had chronic congestive heart failure of long duration. Neither the frequency nor the severity of the clinical attacks of failure or the duration of symptoms varied from hypertensive heart failure unassociated with ventricular bulge.

While cardiac hypertrophy was the single significant feature of both the hypertensive hearts and the hearts in congestive heart failure, there was no exact correlation between the heart weight and the duration of failure. In the symptomless cases and those without congestive failure there was notably little cardiac hypertrophy.

Ventricular aneurysm made the clinical course neither shorter nor more severe. It is evident that the clinical course of heart failure in these cases is that of failure in hypertensive heart disease, and in those without failure, that of arteriosclerotic heart disease.

Summary and Conclusions

1 The clinical and radiographic findings in 43 cases of ventricular aneurysm are reviewed.

2 The clinical course was that of hypertensive or arteriosclerotic heart disease.

3 Ventricular aneurysm appeared in no way to alter the clinical course.

4 The formation of ventricular bulge is probably the result of increase of intraventricular pressure incidental to physical effort or even normal intraventricular pressure in a diseased, thinned-out ventricle.

Case Report

TERAS ANADIDYMUS

MILTON G. POTTER, M D , F A C S , Buffalo, New York

THIS unusual case occurred several years ago in the home of an Italian family.

The patient, aged 34 years, had always been in good health. Menstruation started at the age of 13 and was regular. Her first baby was lost during delivery by a midwife. Another died at the age of 17 months, cause unknown. She had six living children, but there was no previous history of twins. The family history was not remarkable, both parents were alive and well (father was 75 years old and mother, 70 years old). Her two sisters and four brothers were also alive and well, but two brothers and one sister died in early childhood. The husband's family history was not remarkable. One sister had had twins.

According to her physician, Dr. Oscar Stover, the patient, during the prenatal period, claimed she felt different during this pregnancy. She complained of a heavy feeling and was unable to do her work as easily as before. Her abdomen was much larger.

The first stage of labor was uneventful and the attending physician diagnosed the presentation as a frank breech and proceeded under an anesthetic to convert it into a double footling. The body of the child was unusually large and some difficulty was experienced in the extraction

of the legs. Delivery of the body was only partially successful because of some unknown obstruction, and consultation was sought.

The consultant's first impression was a twin pregnancy, because he was able to feel externally two heads. Upon further examination no second body could be discovered.

By means of a curved sharp hook one of the heads was severed, and extraction of the baby was effected. No difficulty was encountered in the delivery of the severed head. The mother made an uneventful recovery.

At the autopsy, this baby weighed fourteen pounds and had two normal-sized heads (see Figs 1 and 2). In addition there were found two spinal columns, two pairs of lungs, two hearts, two stomachs, two livers, two gallbladders, two esophagi, two spleens, one pancreas, one set of pelvic organs, two duodenums which fused together into a single intestinal tract. One set of the organs was very much better developed than the other.

Perhaps the most interesting finding in this autopsy was the discovery of the two hearts within one pericardial sac. This finding should be of interest to the embryologists.

Therapeutics

CONFERENCES ON THERAPY

THESE are stenographic reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital, with collaboration of other departments and institutions. The questions and discussions involve participation by members of the staff of the college and hospital, students, and visitors. This conference was presented before the General Scientific Meetings of the American Medical Association, New York, June 10, 1940. The next report will appear in the April 1 issue and will concern "Treatment of Rheumatoid Arthritis."

Digitalis in Heart Failure

DR EUGENE F DUBOIS. Today we have selected a drug and a condition with which you are all familiar. We shall limit the discussion to the use of digitalis in heart failure.

We try to use the pronunciation "digitālis" but often revert to "digitālis" or "digitālis." It makes little difference which is used. The variation in pronunciation mirrors well the variability in the strength of the drug.

First I shall ask Dr. Walter L. Niles, who has been practicing medicine and teaching students in New York for about thirty years, to give the clinical aspects of the use of digitalis.

Dr. Niles, are you a heart specialist?

DR. WALTER L. NILES. No, Dr. DuBois.

DR. DUBOIS. Then you are the man we want. We do not need a heart specialist for this purpose.

DR. NILES. I believe that every doctor should be trained so that he can intelligently treat patients with heart disease. He does not have to be a heart specialist.

Digitalis is the most effective drug that we possess in the treatment of heart disease, and every physician should be thoroughly familiar with its use. Although William Withering called attention to its value in 1785, it was not until early in the present century that its use became widespread, in large part due to the observations and teachings of Sir James Mackenzie.

Let me mention a few general principles for using digitalis.

In each case enough of the drug must be given to produce digitalization. This is manifested by improvement in the circulation or by toxic symptoms.

The aim should be to secure better circulation without producing toxic symptoms. When neither improvement in the circulation

nor toxic manifestations have developed, it is usually because of insufficient dosage. That is our experience as patients come into the hospital. Few of them have had enough of the drug to produce effective results.

There is a direct relationship between body weight and the dosage of digitalis, although other factors such as the rate of absorption modify it somewhat. The body weight, therefore, serves as a useful guide for effective dosage.

When desired, as in cases with advanced congestive heart failure, the full therapeutic effect of digitalis may be secured within twenty-four hours. The method is first to estimate the theoretic requirement of the patient. Then give one-half the estimated dose. After six hours give one-quarter of the estimated dose and divide the remaining quarter into three doses to be given at four-hour intervals. That is, if you estimate that a patient requires 30 grains of powdered leaves, first give him 15 grains, after six hours give him $7\frac{1}{2}$ grains and divide the remaining dose into three to be given at four-hour intervals. In this way you can watch carefully the development of toxic manifestations, and if they arise—and this is very unusual—before the complete dosage has been administered, it may be stopped. One will seldom, if ever, get into serious trouble following this routine.

It is important before giving any digitalis to ascertain whether the patient has had any of the drug within the past week or two. If so, modify the dosage accordingly and exercise great caution in attempting rapid digitalization.

Following the body-weight method of calculating the dosage of digitalis, we find that a patient of medium size—say about 150 pounds—would require approximately 30 grains of powdered leaf. A small-sized adult

patient would require about 26 grains of powdered leaf, but a large person would need 34 grains or possibly more

About 3 grains of digitals will be eliminated from the body daily. A certain amount must be accumulated in the body before a therapeutic effect will be obtained. Therefore, to obtain such an effect the rate of ingestion must be faster than the rate of elimination. When the therapeutic effect has been secured, a certain amount of digitals, about 3 grains daily, must be given in order to maintain the effect.

The best method of giving digitals is by mouth. It is rarely necessary or advisable to administer it otherwise. Digitals does not produce vomiting except as a toxic symptom, in which case the optimum effect of the digitals on the circulation has already been secured.

The only preparation of digitals used in our clinic for oral administration is the powdered leaves, put up in tablets or capsules. We arrived at this decision after long study and many trials with other preparations.

In rare cases when the patient cannot swallow or when vomiting persists from causes other than digitals therapy, the digitals may be given by rectum. The dosage is about the same and absorption is about as rapid as when given by mouth. The standardized tincture of digitals is used, diluted in 2 or 3 ounces of normal saline solution. One drachm, or 60 minims or 4 cc., equals 6 grains of powdered leaf. Therefore, the average-sized patient, weighing 150 pounds, would require about 5 drachms of the tincture of digitals, which is the equivalent of 30 grains of powdered leaves.

The tincture must always be measured in a glass. It should not be measured by the drop. If you try it out, you will be surprised to find that 30 drops of the tincture will actually amount to only 10 or 15 minims as measured in the glass.

In cases of emergency I prefer to use ouabain (crystallized strophanthin) intravenously. An initial effect may develop within five minutes and the maximum effect will occur within forty-five minutes. It is dangerous to use ouabain if the patient has had digitals within about two weeks. If the patient has not been given digitals within two weeks, inject $\frac{1}{100}$ grain into a vein. If there is no improvement in the circulation after forty-five minutes have elapsed, repeat the dose. Never give more than $\frac{1}{100}$ grain of ouabain

within twenty-four hours. The effect passes off within five days.

Optimum digitalization is the state in which the patient's circulation is most efficient. This varies considerably in different patients, and it can be attained only by prolonged observation and by trial. Patients usually do best with the ventricular rate between 70 and 80. However, some are better with a rate between 50 and 60, while some are at their best with a rate around 90.

The chief indication for digitals therapy is heart failure, with or without auricular fibrillation, with or without flutter, with or without heart block.

Digitals should not be used in preparation for surgical operations unless congestive failure exists. It should not be used in surgical or traumatic shock, in collapse during anesthesia, in the treatment of infectious diseases such as pneumonia or diphtheria, etc., or in neurocirculatory asthenia. A great deal of digitals is wasted on patients of this class.

The only contraindication for the use of digitals is the absence of heart failure.

Suppose a typical example of congestive heart failure comes into the hospital, a young man who gives a previous history of rheumatic fever, who obviously has mitral disease, and whose heart is in auricular fibrillation. He has orthopnea and congestion at the bases of the lung and fluid in the pleural cavity, right or left, his liver is swollen, and he has marked edema of the lower extremities.

I would say the first thing to do with such a patient is to put him in bed and make him just as comfortable as possible.

The next thing to do is to give him a dose of morphine. If he is a medium-sized patient, probably $\frac{1}{4}$ grain. His fluids should be limited to 1,500 cc daily, and his diet should, of course, be light and simple. He won't want much anyhow.

Then begin at once the administration of digitals. If you are using powdered leaves, as I think you ought to, give the man (weighing 160 pounds) 15 grains, in six hours give him $7\frac{1}{2}$ grains and then divide the remaining $7\frac{1}{2}$ grains into approximately three doses to be given at four-hour intervals. If he develops signs of digitals intoxication, of which the most obvious is vomiting, then stop before the total amount has been given.

DR DuBois. Our chief object in these conferences is to make the practical work scientific and the scientific work practical. Next I am going to call on the pharmacolo-

gists We have two here in this session The first, Dr Cattell, will speak on the physiologic aspects of digitalis

DR McKEEN CATTELL In discussing the physiologic background underlying the action of digitalis in congestive heart failure I wish to stress two points—two well-established observations that are fundamental to our understanding of the mechanism of digitalis action.

The first is The work done by a muscle is related to its length A stretched muscle releases more energy than a shorter muscle This is a general rule applicable to all types of muscle and was applied to the heart by Starling, in which connection it is known as Starling's law of the heart It represents the mechanism by which the energy of the heart beat is adjusted to the needs of the body Whenever the venous return is increased—as, for example, following exercise—the pressure rises and the diastolic fiber length is increased The stronger contraction which automatically follows takes care of the extra blood

The same changes occur in weakness of cardiac muscle due to damage from any cause Incomplete emptying is followed by an accumulation of blood and an increased venous pressure The diastolic size of the heart increases and the longer muscle responds with a more forceful contraction. As failure increases, the limits of compensation may be exceeded and the various signs of circulatory failure become manifest

This leads to the important conclusion that the dilated heart of congestive heart failure is not of itself a deleterious phenomenon, rather it represents the means by which the organ adapts itself to an unfavorable situation The same thing holds for the increased venous pressure and the rapid heart rate They are changes tending to correct any disparity between cardiac output and circulatory needs of the body

Where does digitalis enter this picture? That question brings me to the second point I wish to stress Digitalis has a direct action on cardiac muscle which causes it to contract with greater force This was demonstrated by Cushny more than forty years ago and has since been confirmed by many investigators In our laboratory we have been able to show that isolated mammalian cardiac muscle, driven at a constant rate and maintained at a constant length, exhibits an increased force of contraction under the influence of digitalis Thus, independently of any secondary factors such as changes in length, changes in rate, or

nervous or circulatory influences, digitalis results in an increased force of contraction which must be due to a primary action on cardiac muscle I need only ask you to consider the consequence of this action in relation to Starling's law of the heart As the result of the augmented cardiac contraction produced by digitalis, it follows from well-established physiologic principles that the heart rate should slow, the diastolic size decrease, and the venous pressure fall Thus the changes associated with failure subside

It is an interesting commentary that in spite of the facts just related several alternative explanations for the action of digitalis are held at the present time These place the primary action on one or another of the prominent symptoms of congestive failure Thus, some believe that the primary action is to slow the heart, others that it is to reduce the venous pressure by constricting the hepatic veins, and still others that it is to shorten the muscle to a more favorable length It is not possible to review these theories at this time, but it may be stated that the evidence in their support is indirect, and it is clear that the subsidence of these symptoms should follow the improvement in muscle function so characteristic of digitalis action

With regard to the mechanism by which digitalis acts on cardiac muscle to improve the force of contraction we have very little exact information It is a problem of fundamental interest and one on which considerable work is being done at the present time On the papillary muscle of the cat's heart we have found ouabain and digitoxin to be effective in concentrations as low as 1 part in 100,000,000 It is safe to conclude that such a high degree of potency represents an action on the surface of the cell An effect of digitalis which we have been able to demonstrate in our laboratory is the diffusion of potassium outward from the cell Whether this has any relation to its therapeutic action must await further investigation Dr Vischer and his associates at Minnesota have reported interesting experiments in which the changes in efficiency have been studied in the heart-lung preparation of the dog As cardiac failure progresses, there is a decrease in the work done per unit of oxygen consumed—that is, there is a fall in the efficiency of contraction in a mechanical sense When digitalis is added to the perfusing fluid, the heart does more work and it does so without a corresponding increase in the oxygen consumption Thus, digitalis results in improvement in the efficiency at

patient would require about 26 grains of powdered leaf, but a large person would need 34 grains or possibly more

About 3 grains of digitalis will be eliminated from the body daily. A certain amount must be accumulated in the body before a therapeutic effect will be obtained. Therefore, to obtain such an effect the rate of ingestion must be faster than the rate of elimination. When the therapeutic effect has been secured, a certain amount of digitalis, about 3 grains daily, must be given in order to maintain the effect.

The best method of giving digitalis is by mouth. It is rarely necessary or advisable to administer it otherwise. Digitalis does not produce vomiting except as a toxic symptom, in which case the optimum effect of the digitalis on the circulation has already been secured.

The only preparation of digitalis used in our clinic for oral administration is the powdered leaves, put up in tablets or capsules. We arrived at this decision after long study and many trials with other preparations.

In rare cases when the patient cannot swallow or when vomiting persists from causes other than digitalis therapy, the digitalis may be given by rectum. The dosage is about the same and absorption is about as rapid as when given by mouth. The standardized tincture of digitalis is used, diluted in 2 or 3 ounces of normal saline solution. One drachm, or 60 minims or 4 cc, equals 6 grains of powdered leaf. Therefore, the average-sized patient, weighing 150 pounds, would require about 5 drachms of the tincture of digitalis, which is the equivalent of 30 grains of powdered leaves.

The tincture must always be measured in a glass. It should not be measured by the drop. If you try it out, you will be surprised to find that 30 drops of the tincture will actually amount to only 10 or 15 minims as measured in the glass.

In cases of emergency I prefer to use ouabain (crystallized strophanthin) intravenously. An initial effect may develop within five minutes and the maximum effect will occur within forty-five minutes. It is dangerous to use ouabain if the patient has had digitalis within about two weeks. If the patient has not been given digitalis within two weeks, inject $\frac{1}{100}$ grain into a vein. If there is no improvement in the circulation after forty-five minutes have elapsed, repeat the dose. Never give more than $\frac{1}{100}$ grain of ouabain

within twenty-four hours. The effect passes off within five days.

Optimum digitalization is the state in which the patient's circulation is most efficient. This varies considerably in different patients, and it can be attained only by prolonged observation and by trial. Patients usually do best with the ventricular rate between 70 and 80. However, some are better with a rate between 50 and 60, while some are at their best with a rate around 90.

The chief indication for digitalis therapy is heart failure, with or without auricular fibrillation, with or without flutter, with or without heart block.

Digitalis should not be used in preparation for surgical operations unless congestive failure exists. It should not be used in surgical or traumatic shock, in collapse during anesthesia, in the treatment of infectious diseases such as pneumonia or diphtheria, etc., or in neurocirculatory asthenia. A great deal of digitalis is wasted on patients of this class.

The only contraindication for the use of digitalis is the absence of heart failure.

Suppose a typical example of congestive heart failure comes into the hospital: a young man who gives a previous history of rheumatic fever, who obviously has mitral disease, and whose heart is in auricular fibrillation. He has orthopnea and congestion at the bases of the lung and fluid in the pleural cavity, right or left, his liver is swollen, and he has marked edema of the lower extremities.

I would say the first thing to do with such a patient is to put him in bed and make him just as comfortable as possible.

Then begin at once the administration of digitalis. If you are using powdered leaves, as I think you ought to, give the man (weighing 150 pounds) 15 grains, in six hours give him $7\frac{1}{2}$ grains and then divide the remaining $7\frac{1}{2}$ grains into approximately three doses to be given at four-hour intervals. If he develops signs of digitalis intoxication, of which the most obvious is vomiting, then stop before the total amount has been given.

Dr DuBois. Our chief object in these conferences is to make the practical work scientific and the scientific work practical. Next I am going to call on the pharmacolo-

by oral administration as by intravenous injection I believe it is not generally appreciated that only about 10 to 20 per cent of the potent substances in digitalis leaf or the tincture is absorbed from the gastrointestinal tract, whereas in a similar period practically 100 per cent of the dose of these materials is absorbed from the gastrointestinal tract

It requires only 3 cat units of "Digitaline Nativelle" to produce full digitalization by oral administration as against the usual dose of about 20 cat units of digitalis leaf or the tincture

With such materials as these I believe that we are well on the way to the development of digitalis therapy by purified glucosides which are rapidly and completely absorbed from the gastrointestinal tract, and there is an indication that these materials can be extracted from digitalis with such uniformity as to require no biologic standardization

DR DuBois We have already gathered in a good many questions I have tried to distribute them among the different speakers

QUESTION Does a cat unit of different preparations of digitalis produce the same effects in man?

DR DuBois I think that has just been answered in part by Dr Gold How is it, Dr Gold, for the various preparations of powdered leaf and tincture? Are the effects in man still proportional to the cat unit?

DR GOLD For different specimens of the same material the cat method appears to apply fairly satisfactorily One may compare one specimen of digitalis with another by the cat method, but one must not attempt to compare a purified glucoside such as digitoxin with digitalis leaf by any animal method We have evidence that the results are not likely to apply to man unless the testing is done on man directly In our recent studies we found that 1 cat unit of "Digitaline Nativelle" has the effect in man of 6 to 12 cat units of digitalis leaf

QUESTION It has been said that the tincture of digitalis should not be prescribed by "drops" Why not?

DR DuBois Dr Niles emphasized that point The drops of a tincture are very small on account of the alcoholic content It has been my experience that it takes $2\frac{1}{2}$ to 3 drops of tincture to make 1 minim, so that there is a great deal of difference between the minim actually measured in a glass and the drop Of course, in the case of a watery solution a drop and a minim are much closer together

QUESTION In your case of decompensated rheumatic mitral disease, what will be your advice regarding digitalis when the patient leaves the hospital fully compensated—especially the dose, amount and frequency?

DR NILES I would prescribe 3 grains of digitalis leaves to be given in one dose, that is, once a day The most convenient time is after breakfast It probably should be kept up over a long time or indefinitely However, that dose might not be enough for that man or it might be too much One must find the dosage at which he feels best Many patients learn by themselves They leave out digitalis for a day or two, or when they feel a certain way they may take an extra dose on some other day, but approximately 3 grains of digitalis leaves is the average daily dose

DR DuBois There are several questions here with regard to the use of digitalis in coronary thrombosis

QUESTION Would you use digitalis or strophanthin in acute coronary occlusion (a) without heart failure and (b) with heart failure?

DR NILES My own feeling is that without heart failure one would not use digitalis I see no indications for it With heart failure in any form I certainly would give digitalis There are certain theoretic objections described in the texts, such as that the increase of strength of the ventricular contractions might produce rupture, but I think they are really unimportant Therefore, I do give digitalis to patients with coronary thrombosis provided they have any form of heart failure

QUESTION Why not use digitalis in auricular fibrillation after coronary thrombosis? When is it safe after coronary thrombosis?

DR NILES I think it is safe any time after coronary thrombosis when there is heart failure

If the patient has auricular fibrillation following coronary thrombosis and develops a rapid ventricular rate, he will almost certainly have some indications of heart failure Therefore, I would give the patient digitalis In other words, it all comes back to the question of heart failure

I think that answers all of the questions concerning the use of digitalis in coronary thrombosis

QUESTION Did Dr Cattell mean to imply that digitalis has no slowing effect on conductivity of the heart beat or on the vagus? Does not digitalis have a primary action on auriculoventricular conduction which would

which the heart carries on its work. It not only does more work but it does it more efficiently.

DR DUBOIS. By this time a good many of you have questions. I shall ask Dr Milhorat to hand out cards in case you care to write them down. We should like to have as many as possible.

Dr Harry Gold will continue the discussion of the pharmacologic aspects of digitalis preparations.

DR HARRY GOLD. I am going to confine my remarks to that aspect of the pharmacology of digitalis which has to do with the choice of preparations.

Dr Niles stated that the adult patient of average weight requires about 30 grains of digitalis to produce the full therapeutic effects. I presume he has reference to the U S P digitalis leaf.

It has been our general experience that digitalis leaf meets the requirements of digitalis therapy as satisfactorily at least as any of the specialties of digitalis in the form of extracts or mixtures for oral administration.

There are a few matters concerning digitalis leaf or the tincture, however, which require special attention because digitalis preparations show wide differences in their composition and potency. A point that is perhaps not generally known is that digitalis of the present *Pharmacopœia* is about 50 per cent stronger than digitalis of the previous *Pharmacopœia*. This means that for every 15 minims of tincture of digitalis which we prescribed prior to 1936 we now prescribe only 10 minims of the tincture, and that for every $1\frac{1}{2}$ grains of digitalis leaf which we prescribed prior to 1936 we now prescribe only 1 grain of digitalis leaf.

The U S P digitalis is standardized by the frog method in accordance with the technic outlined in the *Pharmacopœia*. We must not assume, however, that because U S P digitalis leaf is standardized it is all of uniform potency. The *Pharmacopœia* itself allows a 40 per cent range between the weakest and the strongest preparation.

More important, perhaps, than this is the fact that digitalis preparations of commerce show a much wider range. We recently assembled a group of preparations of the most popular brands of the tincture of digitalis. We assayed them by the cat method, and we found wide variations—all the way from 0.35 cc per cat unit for the strongest preparation of the tincture to 0.96 cc per cat unit for the weakest one. The strongest preparation

is then about three times as potent as the weakest, a difference of about 300 per cent for preparations of the tincture of digitalis which are labeled U S P XI.

In the case of a patient who is seriously ill and requires rapid digitalization by very large doses, the importance of the matter is self-evident, whether the digitalis is one-third as strong or three times as strong as we expect it to be.

However, when we pursue a technic of digitalization along the lines described by Dr Niles, in which we divide the full dose into fractions, the marked variation in potency of preparations is not quite so serious because in such cases one gives more or less of the drug, being guided by the development of effects and symptoms.

I see no satisfactory solution at the present time for the difficulties of wide variations in the potency if we continue to depend on preparations of the whole digitalis leaf. We shall be better off, to be sure, if at least we keep aware of the fact that these differences in potency of preparations labeled U S P XI exist.

I might add that the New York Heart Association has solved this problem for itself by purchasing a large batch of digitalis leaf, enough to last three, four, or five years. This is physiologically assayed by the cat method and made up into tablets of varying sizes. This insures uniformity of the digitalis for at least that period of time for the sixty member clinics which take care of about 20,000 cardiac patients.

The real solution of the problem of variable potency of digitalis preparations lies in the discovery of the purified glucosides which might be obtained in crystals of uniform strength which will not require biologic standardization. During the past year we have made some studies along these lines, and the results offer considerable promise. Our experience with man is similar to that of Hatcher and others with animals and shows that digitoxin-like materials obtained from digitalis leaf possess extraordinarily valuable properties. We have now had some experience with "Digitoxin-Merck" and more with the crystalline material of the French preparation known as "Digitaline Nativelle".

These two materials, although not identical, are similar in important respects. They are absorbed from the gastrointestinal tract almost as well as a dose of strychnine or a dose of quinine. Results in animal experiments show that a dose is almost as effective

of heart failure If there is heart failure, give digitalis If there is no heart failure, do not give digitalis

It has been customary in many clinics, as it was with us, routinely to digitalize patients with pneumonia At Bellevue Hospital we carried out quite an extensive study a few years ago and found the mortality actually higher in those patients who were digitalized We no longer routinely digitalize patients with pneumonia

QUESTION If compensation occurs with bed rest, is digitalis indicated?

DR NILES I would not wait for the patient to compensate with bed rest alone I would give him digitalis

QUESTION What is the shortest time that one can safely digitalize a patient? In what manner of administration?

DR NILES One can do it in eighteen hours with perfect safety by using digitalis leaves given by mouth One may do it more quickly by using crystallized strophanthus intravenously It is seldom necessary to be in such a hurry

QUESTION What is the reason for the morphine that is given to the patient when first seen?

DR NILES It is given to the patient to make him more comfortable This in turn reduces the strain on his heart I believe

that morphine is a highly valuable adjuvant to digitalis in treating heart failure

QUESTION Is there any difference between "fat-free" digitalis and digitalis not so treated, with regard to the production of nausea and other unpleasant symptoms?

DR GOLD The answer is "No" The official tinctures of digitalis contain little fat There was a belief that the fat in digitalis was responsible for the nausea and vomiting We now know that this is not so and that nausea and vomiting generally result from the systemic action of toxic doses of the glucosides after absorption

QUESTION Is there any further indication for infusion of digitalis?

DR GOLD The answer to that is "No"

QUESTION What is the technic of digitalization with digitonin-like materials?

DR GOLD In the case of "Digitaline Nativelle" the amount that produces full therapeutic effects is approximately 1 to 1.25 mg, and that total amount may be given at one time or it may be divided into three or four fractions, each fraction given at about three- or four-hour intervals A slower technic is to give approximately 0.25 mg every day, and in five or six days the patient is fully digitalized The same daily dose may then be continued for maintenance This applies to the average ambulant patient

R A JOB

The steps which lead to the establishment of a former tuberculosis patient in a job are extremely important to the patient himself, to his family, to the people with whom he will be working, and to the community at large They are important to the patient because they may determine whether or not he will live They are important to the patient's family and his future co-workers because, if his disease reactivates, he may infect them The community is vitally concerned not only from the standpoint of preventing relapses with consequent infection of others, but also from the economic aspect of protecting the thousand or more dollars it has invested in treatment of the patient—

Quoted in Minnesota Medicine

THE WHY OF THE MEDICAL SOCIETY

"The well-conducted medical society should represent a clearinghouse, in which every physician of the district would receive his intellectual rating, and in which he could find out his professional assets and liabilities We doctors do not 'take stock' often enough, and are very apt to carry on our shelves stale, out-of-date goods The society helps to keep a man 'up to the times,' and enables him to refurnish his mental shop with the latest wares Rightly used, it may be a touchstone to which he can bring his experiences to the test and save him from falling into the rut of a few sequences It keeps his mind open and receptive, and counteracts that tendency to premature senility which is apt to overtake a man who lives in a routine"—Osler

THE GANG THAT RUNS THINGS

"Ah, what's the use?" said the enthusiastic young physician. "I tried to horn in here, but only busted my horn. There is a gang that runs this medical society, and outsiders have no more show than a snake has hips!"

The past-president, to whom this remark was directed, lighted an obese cigar and spoke

"You are right, young man, and you are wrong," he said. "By this statement I mean that you are right about a 'gang' running the society. There's a 'gang' running every organi-

zation on earth. If there wasn't, there wouldn't be any organizations. On the other hand, you are wrong when you say you tried to horn in and couldn't. You did not go about it right. Any good guy who wants to horn into any gang has to know the password, and I will give it to you in strictest confidence. These words are 'What can I do to help?' Any man who will use those words will find himself as busy as a one-armed piano player with a bad case of hives!"

—*Detroit Medical News*

account for the slowing of the ventricular rate in auricular fibrillation?

DR CATTELL I am glad that question has been raised because one of the well-known actions of this group of drugs is the direct one on conduction between the auricle and ventricle, and it is undoubtedly true that when a sufficiently large dose of digitalis is given slowing of the rate may result from that cause. However, it can be shown that when the auricle is fibrillating, even when digitalized, the rate is under the control of the vagus mechanism, for the heart of patients under these conditions responds to exercise or atropine with an increase in rate. Under these circumstances there is every reason to believe that an improvement of muscle function would be followed by a slower rate, i.e., the normal physiologic response prevails. That is the case with ordinary therapeutic doses, but with larger doses the direct effect on conduction plays a large part. This is proved by the use of atropine, as in Dr Gold's recent studies, which loses most of its effect on the heart rate when sufficiently large doses of digitalis are given.

QUESTION Dr Niles states that 3 grains of digitalis daily is necessary to keep a patient digitalized. We have been taught that $1\frac{1}{2}$ grains only is necessary. What is the reason for this discrepancy?

DR GOLD I believe that when Dr Niles spoke of 3 grains he referred to the average patient, but there are some who require less and some more. However, I think the question brings up a point of importance and related to the matter that Dr Cattell has just discussed. In one and the same patient one sometimes finds that $1\frac{1}{2}$ grains or 3 grains seem to be equally effective in keeping the heart rate in auricular fibrillation at a given level. By way of illustration, you digitalize a patient fully with 25 grains in the first twenty-four to forty-eight hours, reducing the ventricular rate to 70 a minute. Then you give that patient $1\frac{1}{2}$ grains daily and the rate remains at that level for months. But you might double the dose without sending the rate any lower. When the patient received $1\frac{1}{2}$ grains daily with the rate at 70, a dose of atropine to paralyze the vagi sent the rate to 150 or 160 a minute, whereas, when the rate was maintained at 70 by 3 grains daily, the paralytic dose of atropine sent the rate only up to about 100 a minute. In the latter case the patient was much less susceptible to marked fluctuations in ventricular rate with slight effort, since the mech-

anism of slowing was one of direct action on the auriculoventricular conduction, whereas in the first instance the mechanism of slowing was through the vagus as outlined by Dr Cattell.

QUESTION Are some digitalis glucosides superior to others with regard to their action on cardiac muscle and to the incidence of toxic effects?

DR GOLD There is no convincing evidence that any digitalis glucoside is superior to any other from the standpoint of the range between the therapeutic dose and the toxic dose. Nevertheless, with a preparation that is more rapidly absorbed than another, toxic symptoms are less likely to be produced, because slow absorption and irregular absorption go hand in hand.

QUESTION How stable is the tincture of digitalis or at what age does it become worthless?

DR GOLD We have had tinctures of digitalis in the laboratory which have been standing for years, and they have retained their activity as tested by the cat method. There is a tendency for the tincture of digitalis to show a loss of activity by the frog method of assay in the course of months and sometimes years, but there is no good evidence that such tinctures are materially weaker in man.

QUESTION Do you advise digitalis in rheumatic heart disease with a high heart rate?

DR NILES Certainly not unless there are signs of heart failure.

QUESTION Is there any contraindication to digitalis usage in a failing heart following prolonged hypertension?

DR NILES Prolonged hypertension is no contraindication. There is certainly every indication for the use of digitalis from the effects of which the blood pressure will probably fall. It is surprising how well patients of this class do for long periods of time on digitalis.

QUESTION The statement was made cautioning against the use of digitalis in pneumonia. With definite, congestive heart failure complicating pneumonia, would it be better to use digitalis or wait for the finding of right heart failure at autopsy?

DR NILES That is a sort of cryptic question which demands a straight answer. If congestive heart failure complicates pneumonia one uses digitalis, of course. In fact, the sum and substance of the indications for the use of digitalis depend upon the existence

into formal commission under command of Captain L W Johnson, MC, U S Navy, on October 5 of this year, the exercises were held on a pier in the North River where the hospital-to-be was still a vast number of crates and boxes that loaded the pier to capacity. Three weeks later the hospital in boxes left New York on the Navy Transport "Henderson" for Guantánamo, Cuba. The hospital staff went with it. Besides the medical and dental officers, nurses, and hospital corpsmen, the staff included navy carpenters, machinists, plumbers, and electricians. Five days later the "Henderson" arrived at Guantánamo and started to unload. Three weeks later the staff had erected and equipped a hospital from the mass of boxes, and it was in operation. The 500 cots and beds for patients are in tents, as are the living quarters of the staff. A prefabricated wooden building houses the operating room suite. The staff mechanics constructed wooden buildings for the laboratory, x-ray department, dental offices, physical therapy department, galley, bake-shop, mess halls, and laundry. The equipment of the hospital, besides three x-ray machines and physical therapy and the usual hospital equipment, includes a 90-watt electric power plant, a refrigerating plant that can make a half ton of ice and freeze 200 quarts of ice cream daily, twenty-eight automatic kerosene-burning refrigerators, a sewage disposal plant, a water purification and filtration plant, laundry equipment, a power insecticide sprayer, and last but not least two sound, moving-picture projectors. Water storage is provided for in 16,000-gallon metal containers and in the Army-type canvas tank. To the Army we are indebted also for the new type, field ranges used in the galley. Four ambulances, five trucks, two motorcycles, and a station wagon provide transportation.

Minor mistakes in equipment and operation have been corrected. The staff has been trained and can move to another base whenever necessary. In case of mobilization for war, the fleet might find it strategically advisable to base on Trinidad, on Bermuda, or on some South American station. To that base would go the hospital. It is believed that with the experience already acquired the staff can dismantle it, put it on board ship, and reassemble it at a new base in six weeks. It is planned to construct and assemble at least one more of these base hospital units.

Portable hospital units, similar to those used by the Army, have been developed by the Navy for use with the marine expeditionary

force. Each unit comprises seventy-two hospital beds and twelve tents transported in fast, motorized ambulances. Field surgical instruments of new lightweight design will be carried.

Personnel Preparedness

How is the medical department of the Navy prepared to care for the present navy and marine corps force of 210,000 men and "to keep as many men at as many guns as many days as possible," and how will it be prepared for a personnel expanded to nearly three times that number?

The hospital corpsmen who are our male nurses and technicians are young men carefully selected from the newly enlisted apprentice seamen at the training stations. They are sent to hospital corps schools for from four to six months and then to naval hospitals where their training is continued. As they are promoted they are given opportunities to train as laboratory, x-ray, and physical therapy technicians, etc. The increase of the hospital corps will take place as part of the regular increase of the Navy and with the addition of naval reserves.

The female nurse corps is made up of registered nurses who are graduates of recognized civilian institutions. The Reserve Corps of nurses is similarly made up, and the Red Cross is doing invaluable work in organizing it.

Doctors and dentists of the regular Navy are commissioned directly from civil life and must be under 32 years of age when commissioned. Doctors must have completed at least one year's internship, though a limited number of fourth-year students are given acting appointments, their internship in the Navy, and a commission afterward.

In normal times the newly commissioned medical officers are sent to a naval hospital for duty until the following September and are then sent to the Naval Medical School in Washington for the basic course in medicomilitary medicine. Included in this course are three weeks of chemical warfare at Edgewood Arsenal, Maryland, and three weeks of field service with the marines at Quantico, Virginia.

From that time onward opportunities are offered for continuous advancement in the way of postgraduate education. To be of full value to the service, the young officer must study and develop special qualifications and, at the same time, must take his share of rotation on ships at sea, for the mission of the

Special Article

MEDICAL PREPAREDNESS IN THE NAVY

CAPTAIN E C WHITE, M C , U S Navy, New York City

THE present defense policy of the United States calls for a navy that will be prepared to defend our shores on the Atlantic and on the Pacific—and even defend South America—against any enemies by whom they may be attacked. This navy is to be built up as soon as possible, for we know not how soon that attack may take place.

The present authorized building program will increase the number of battleships from fifteen to thirty-two, the aircraft carriers from six to eighteen, and approximately double the number of cruisers, destroyers, and submarines by 1946. To support this fleet of fighting craft, supply and ammunition ships, submarine and aircraft tenders, tankers, and other auxiliary ships are being constructed or are being taken over from the Merchant Marine and converted to their naval purpose.

The aviation branch is to be increased from 3,000 pilots to 22,000, with 15,000 planes. The Marine Corps is to be increased by 33 per cent to 50,000. Navy yards and training stations have already been expanded. New naval bases and air stations are being established on the mainland, in Alaska, on the islands of the Pacific, and in the West Indies. The present combined total of 210,000 Navy and Marine Corps personnel will be expanded to about 500,000.

In this preparedness program what part does the medical department play? How does it fulfill its function at present, and how will it fulfill its function in the expanded navy? Its preparedness may be divided into (1) materiel preparedness and (2) personnel preparedness.

Materiel Preparedness

The eighteen existing naval hospitals are being enlarged and five new ones are being constructed. The new ones are at the Naval Air stations at Jacksonville, Florida, and San Juan, Puerto Rico, the Submarine Base, Coco Solo, Canal Zone, the Naval Station, Guantánamo Bay, Cuba, and the Marine

Base, Quantico, Virginia. These all replace dispensaries and four of them are in the West Indies—Canal Zone area.

The "Hospital Ship Relief," designed and constructed as a hospital ship, was commissioned in 1919. It can accommodate 500 patients and carries a staff of medical and dental officers, nurses, and hospital corpsmen. It has served its purpose well, cruising with the fleet wherever it goes. But one hospital ship cannot adequately serve a two-ocean navy. We will need more. Last September the Navy purchased the 13-year old, 6,200-ton "Iroquois" from the Grace Line and is now converting it into a hospital ship which will be renamed the "Solace" after the first hospital ship of the American Navy. It will accommodate 438 patients, have an elevator, operating rooms, x-ray plant, and all other equipment of a first-class hospital. The "Iroquois," you may remember, got into the newspaper headlines last July on one of its last trips. It was held up by a submarine in South European waters and it was only after a lengthy argument over the radio that it was allowed to proceed. The submarine thought it was a disguised British ship, and our hospital ship-to-be came very near indeed to being sent to the bottom of the ocean.

Ambulance ships will be necessary auxiliaries, particularly if the fleet is operating at a distance from the coast bases. No ships have been or will be constructed specifically for that purpose, but the Marine Corps transports, "McCawley" and "Barnett," recently converted from Merchant Marine liners, have been so designed as to be adaptable for use as evacuation ambulance ships, each with a capacity for about 2,000 wounded. Other ambulance ships can be converted from luxury liners with relatively little work.

An interesting and rather experimental venture in the way of hospitals is the Navy Mobile Base Hospital. It is a complete hospital, so planned and organized that it may be moved from one base to another as the fleet or marine expeditionary force may change its operating base.

When Mobile Base Hospital No. 1 was put

Read before the New York County Medical Society on December 23, 1940

District medical officer of the Third Naval District

the horizon Their planes have been driven off by the planes from our aircraft carriers Retreat from general quarters is sounded All doors are opened, and the crew leave their battle stations The surgeons and their assistants return to the sick bay and operating room on the upper deck. Wounded men are redressed, emergency operations are performed, and the dead and wounded are placed on deck ready for transfer Soon hospital ships and ambulance ships come up over the horizon at full speed to meet the Battle Fleet. They have been kept well in the rear during the battle Boats are lowered, and the wounded and the dead removed from all fighting ships To the hospital ships go the most seriously wounded and those requiring immediate attention Awaiting them on board are hospital units of prominent specialists from leading civilian hospitals, besides medical officers of the Regular Navy To the ambulance ships go the rest of the wounded and the dead On those ships also are hospital units and members of the Volunteer Naval

Reserve All wounded will be well cared for

The enemy fleet has been defeated but not destroyed Our fleet may have to fight another battle in a few weeks, perhaps sooner The hospital and ambulance ships are ordered to proceed at full speed to Guantánamo Bay and Bermuda, unload, and rejoin the fleet without delay There is a new naval hospital at Guantánamo, and Mobile Base Hospital No 1 has recently been established in Bermuda At both of these hospitals members of the Volunteer Medical Reserve are on duty, standing by with their regular service associates

Later, naval transports will move the wounded and dead from these outlying hospitals to naval hospitals on the mainland There again we will find hospital units of prominent surgeons, internists, and other specialists—medical officers of the Volunteer Naval Reserve They have patriotically left behind their private practices to devote their services to their country, and they have helped to make the medical department of the Navy prepared

MANY VICTIMS OF BURNS COULD BE SAVED BY TRANSFUSIONS OF PLASMA PROTEIN

Of the 5,000 deaths each year in the United States attributed to the effect of severe burns, many could undoubtedly be avoided by adequate treatment by means of transfusions of plasma (fluid portion of the blood) protein, aimed at replacing the substances lost by the body in this serious type of injury, Dr Robert Elman, St Louis, declares in the *Journal of the American Medical Association* for January 18

The pessimism often expressed as to the outcome of extensive burns is fallacious, Dr Elman believes It is based "on the inference that, since large areas of skin are involved, it will be impossible to obtain a sufficient amount of normal skin for skin grafting later This idea

is often erroneous as far as the burn turns out to be first or second degree and therefore requires no skin grafting whatever It is obvious then that, if these patients could be carried over the acute stage of their disease and the general manifestations corrected, not only would lives be saved but further treatment would become unnecessary "

Dr Elman advocates that the protein lost because of severe burns be replaced by means of transfusions of plasma. Although some authors have advocated the administration of sugar and salt solutions, it is his opinion that the giving of these fluids alone in burns "is not only often ineffective but may, if excessive, be dangerous "

OR ICE-CREEPERS FOR THE COW-SLIPS

A young farmer went into a store to get some feed for his hogs and was waited on by a new clerk, a young lady

"I want some shorts for my hogs," the farmer said.

"Oh, you're one of those smart guys," the lady clerk retorted. "Next I suppose you'll be coming in here for some brassieres for your cows."

—*Certified Mill*

A MANY-COLOR CAMERA

Physicians intending to add pictorial records to their case histories will be interested in the new color-flash, clinical camera which has just been perfected with the assistance of active practitioners, says the *New York Medical Week*. This camera makes pictures in color, as well as black and white, in the various body orifices, and by a method that is so simple that any doctor can do good clinical photography

Navy requires efficient medical department activities at sea

Officers who show aptitude are sent to civilian institutions for courses in various specialties, such as surgery, internal medicine, etc., or they are sent to Navy or Army schools for instruction in aviation medicine, tropical medicine, submarine medicine, or deep-sea diving. Medical officers are encouraged to become Associates and Fellows of the American College of Surgeons and American College of Physicians and to take the American Board examination in their specialty.

But in time of war or national emergency it is upon the Volunteer Naval Reserve that the medical department of the Navy must rely for a rapid increase in personnel. The Naval Reserve was established in 1916 and reorganized in 1925 and again in 1938. It includes both line and staff and is divided into two classes, the Volunteer General and the Volunteer Special. The doctors in the Volunteer General Reserve must be under 35 years of age when commissioned and may be assigned to any of the naval duties ashore or at sea to which medical officers of the Regular Navy may be assigned. In the Volunteer Special Reserve doctors who are qualified specialists are commissioned up to 50 years of age. It is the intention to use them only in their respective specialties, either as individuals or in hospital units. The usual hospital unit is made up of eight doctors, each of a different specialty, and one dentist. They will be used in naval hospitals ashore or beyond the sea or on hospital or ambulance ships.

Doctors are still being enrolled, both in the Volunteer General Reserve and in the Volunteer Special Reserve. In the General Reserve in particular there are still many vacancies for young doctors under 35 years of age. This class includes interns and residents, who are placed on a deferred list to be called to active duty only in case of emergency.

A Nation at War

With the medical department organized and prepared in materiel and in personnel, let us see what part it will play when the nation is at war. Let us go to sea with it on one of the new 35,000-ton battleships as the fleet seeks the enemy.

The enemy fleet is sighted, general quarters is sounded on bugle, gong, and loud-speaker, officers and men rush to their battle stations, the medical department personnel leave their sick bay and beautifully equipped operating

room on one of the upper decks and hurry down to their battle dressing stations several decks below and behind the heaviest portion of the armor plate. Already equipped with portable operating tables, sterilizers, instruments, supplies, and great quantities of sterile shell and gunshot wound dressings, the battle dressing stations are soon ready for battle.

The battle begins. Enemy airplanes drop bombs on our deck, some of the shots from the enemy ships' big guns reach their target. Several of our guns are put out of action, men are killed and injured. Repair parties are rushed immediately to every point where damage is done. A hospital corpsman is a member of each party, and he supervises the first aid given to the injured, paying particular attention to those with minor injuries who may be returned immediately to their guns. The crew has been well trained to take first-aid packages from the boxes marked with a Red Cross and installed in all parts of the ship. If the injured man still bleeds after the occlusive dressing is applied, a tourniquet is put on. If he is in pain, a syrette of morphine is taken from the box and injected, and the man is so tagged. The dead are placed to one side. The battle goes on. Soon there is a lull—the enemy ship that has engaged ours is disabled. Word goes out from the commanding officer in the conning tower. Some water-tight doors are opened. Bandsmen trained as stretcher bearers and led by a well-trained hospital corpsman rush out with wire mesh stretchers, gather in the wounded, and take them down to the battle dressing stations before the firing can be resumed.

In the battle dressing stations the surgeons and their assistants are scrubbed up and ready. They operate if necessary, change dressings, remove tourniquets, and administer morphine. The dental officer and the chaplain take the names of the wounded and see that each is properly tagged with degree of seriousness and need for further urgent attention. Wounded are placed in bunks, and the dead are tagged and placed to one side in the hammock netting.

The battle is rejoined, another enemy ship is firing at us, other lulls occur in the battle. Some of the men brought to the dressing stations have been burned by mustard gas bombs dropped by enemy planes, and others were picked up from the sea—they were members of the crew of an enemy plane shot down by our anti-aircraft fire.

At last the battle is ended—the enemy ships have been sunk or disabled or have fled over

Inside the black, all-metal kit was the following inscription "Presented to our brother physicians of England in honor of Maurice J Dattlebaum, M.D., F.A.C.P., president of the Medical Society of the County of Kings and Academy of Medicine of Brooklyn, N Y, U S A., by his medical friends, January 28, 1941"

Monroe County

A city contract for eye examination of 1,000 indigent Rochester school children has been accepted by the county society's eye defect committee.

The committee, headed by Dr Leonard W Jones, also announced it stood ready to aid in a program of rehabilitating men rejected because of eye defects in the draft and in industrial defense training

Nassau County

Legislators should look to the medical profession instead of "social theorists" and "professional politicians" in writing a national health program for America, Dr Nathan B Van Etten, president of the American Medical Association, told the county society and auxiliary at Cathedral House, Garden City, on January 28

The program was sponsored by the auxiliary, with Mrs Arthur C Martin, of Old Westbury, its president, presiding. She introduced Dr Aaron L Higgins, of Rockville Centre, president of the society, who conducted the brief business session of the men's group

Saying that defense against disease was as important as defense against an enemy, Dr Van Etten asked the physicians to take seriously the matter of drafting a national health program.

"The press announces a new Wagner health bill," he said "Will the senator ask the help of the medical men in framing this new proposal? Or will he again look to social theorists to write his legislation for him?"

Every health agency in the country, he asserted, should be mobilized for national defense and a national health department created with a secretary of health occupying a similar position in the federal government as, for example, the secretary of labor or treasury

Dr Van Etten criticized groups that are leaping to mask their own private workings under the guise of national defense.

"Just now," he declared, "the national emergency seems to have created conditions which will be made the excuse for jumping into hastily conceived plans for national service."

Earlier, an informal dinner for the speaker was held at the Garden City Hotel. Members of the society and auxiliary's executive committee were guests

New York County

The following scientific program was presented before The New York Academy of Medicine at its meeting on February 6. Newer Surgery of the Heart and Large Vessels—(a) Medical aspects, by Dr H M Marvin, associate clinical professor of medicine, Yale University School of Medicine, (b) Surgical aspects, by Dr William DeWitt Andrus, associate professor of surgery, Cornell University Medical College

The New York Dispensary founded by the medical profession of New York City, celebrated

its one hundred and fiftieth anniversary on February 1

"The year 1940 gave New York City the lowest death rates ever experienced for infant and puerperal mortality, pulmonary tuberculosis, diphtheria, pneumonia, and typhoid fever," said Health Commissioner Dr John L Rice in his annual report submitted to Mayor LaGuardia "The total number of deaths from all causes at all ages amounted to 76,008, giving a general death rate of 10.3 per 1,000 population. The birth rate recorded in the city was definitely higher than it has been for several years"

Rensselaer County

Dr Stanton Perry Hull, 54, of Troy, who died on January 24, was a former president of the New York State Sanitary Officers' Association. He was also prominent in many local activities and in fraternal and religious organizations

Schenectady County

Dr I S Wechsler, clinical professor of neurology at Columbia University, lectured on "Recent Advances in Neurology" at a meeting of the county society at Ellis Hospital on February 4

Suffolk County

At the March meeting of the Hampton Clinical Society, which will be held at the Southampton Hospital, Thursday, March 27, at 9 p.m., there will be a talk on "Pathology of the Uterus," with moving pictures and gross and microscopic specimens

All members of the county society who may be interested are invited

The February programs of the Hampton Clinical Society were as follows: February 13—

(1) Physiotherapy in Infantile Paralysis, by Nils Berglund, Masseur, (2) Occiput Posterior Presentation, by Dr George H Schenck, (3) Films Obstetric February 27—(1) Jaundice with Case, by Dr Herman Rubler, (2) Osteogenic Sarcoma, by Dr Perry Elmont, (3) election of officers, (4) social hour

Westchester County

The county society met with the Westchester Society of Gastroenterology at the New York Hospital, Westchester Division, on February 18 and heard an address on "Clinical Uses of Long Intestinal Tubes," by Dr William Osler Abbott of Philadelphia

Dr Halcyon Halsted, of Pelham Manor, has been elected president of the New York Society of Industrial Physicians and Surgeons

Dr Halsted succeeds Dr Harry Van Ness Spaulding, retiring president, and Dr F Albee, former president

More than two hundred friends, patients, and professional colleagues honored Dr Henry T Kelly, of White Plains, a past-president of the county society and former editor of its *Bulletin*, at a dinner at the Westchester Country Club on January 11 in celebration of Dr Kelly's completion of forty years in practice in White Plains

Dr Kelly is chief of staff of the White Plains Hospital, and the toastmaster at the dinner was Mr John W Appel, Jr, president of the White Plains Hospital Association. Other speakers

County News

Albany County

The county society, at its meeting on January 22, heard a paper on "Surgical Treatment of Deafness," by Dr Leighton F Johnson, professor of laryngology, Boston University School of Medicine

Dr Arthur W Wright, professor of pathology and bacteriology at Albany Medical College, and William G McEwan, vice-president and secretary of the Morris Plan Industrial Bank of Albany, spoke at a "health defense" meeting at Albany Law School auditorium on February 6—one of a series sponsored by the public relations committee of Albany Hospital and Medical College in cooperation with the Albany County Medical Society and Albany Hospital Council

Bronx County

The county society is cooperating with several other medical and health bodies in sponsoring a series of educational meetings on "The People's Food," running from January 23 to March 20 in the Mott Haven Health Center, discussing the elements of food, their functions in the body, their best sources, diseases caused by food deficiencies or excess, the prevention of these diseases, food purchasing, and budgeting

Broome County

A motion picture in colors on "Eclampsia," by Dr Joseph B De Lee, of Chicago, was shown at the meeting of the county society on February 11 Discussion was opened by Drs S B Blakely, M A Carvalho, G R Cheatham, H I Johnston, C J Marshall, and C H Topping

The county society's radio speakers on the four Thursday evenings in February were Drs Carlton H M Goodman, Frank Paul Kane, H I Johnston, and Stuart B Blakely

The Endicott-Johnson Medical Department has invited the county society to attend its annual meeting and program on April 15

Chautauqua County

The Jamestown Medical Society held a dinner meeting on January 30, at Hotel Jamestown, with covers for thirty Dr D C Perkins presided Guest speaker was Dr J L Reycroft, of Cleveland, assistant professor of obstetrics and gynecology at Western Reserve University, who spoke on "The Treatment of Sterility in the Female" A discussion followed

Dutchess County

At its meeting on February 8, the county society paid tribute to the late George V L Spratt, former mayor and counsel to the society over a long period of years, in a testimonial letter to Mrs Spratt The society also honored Dr Howard P Carpenter, its secretary for 26 years, now retired, and Dr John S Wilson, member, who has been practicing fifty-four years

Erie County

Topics and speakers at recent meetings of the Buffalo Academy of Medicine were as follows

Section of Pathology, January 29, "Pathogenesis of Tuberculous Lesions in Adults," by Dr Kornel Terplan, Buffalo

Section of Surgery, February 5, "Problems in the Surgical Treatment of Thyroid Diseases," by Dr Robert Scott Dinsmore, Cleveland

"Medical Social Work, Medical Education and Medical Service," by Dr Jean Alonzo Curran, dean and acting president, Long Island College of Medicine, was held at Hotel Statler on February 19

The annual supper dance of the Erie County Rural Medical Club was held on February 6, at the Trap and Field Club

Kings County

Dr William C Meagher was named president-elect of the county society, to take office in January, 1942, at the annual meeting on January 21 Dr Maurice J Dattlebaum, who was chosen president-elect last year, took office at the meeting

Other officers elected for 1941 were Dr Leo S Schwartz, vice-president, Dr Thomas B Wood, secretary, Dr Benjamin M Bernstein, associate secretary, Dr Irwin E Sims, treasurer, Dr Abraham Klein, associate treasurer, Dr Jaques C Rushmore, directing librarian, and Dr Edwin P Maynard, Jr, associate directing librarian and curator

The board of trustees of which Dr John J Masterson was elected chairman, Dr Thomas A McGoldrick, vice-chairman, and Dr Augustus Harris, secretary, includes Dr Frank L Babbott and Dr Albert F R Andresen, one-year terms, Dr Harris, Dr Alexander L Louna, and Dr McGoldrick, two-year terms, Dr Charles A Anderson, Dr John B D'Albora, and Dr Masterson, three-year terms, Dr John L Bauer, Dr Thomas M Brennan, and Dr Phillip I Nash, four-year terms, and Dr Daniel A McAteer, Dr Sydney Nussbaum, and Dr Joseph Tenopyr, five-year terms

The board of censors, of which Dr John J Gainey is senior censor and Dr A W Martin Marino is secretary, includes Dr Merrill N Foote, Dr Gainey, and Dr Robert A Wilson, one-year terms, and Dr Harry Feldman, Dr Edwin A Griffin, Dr Marino, and Dr Abraham M Rabiner, two-year terms

Delegates to the Medical Society of the State of New York for 1941 are Drs E Jefferson Browder, D'Albora, Feldman, Charles F Fisher, Irving Gray, Walter D Ludlum, Harvey B Matthews, McAteer, Meagher, Nash, and Sims Delegates to the State Society for 1941-1942 are Drs Anderson, Andresen, Bernstein, Dattlebaum, Griffin, Klein, Masterson, Charles F McCarty, McGoldrick, Irving J Sands, Schwartz, and Wood

At the dinner for Dr Dattlebaum on January 28, at the Towers Hotel, a first-aid kit for the British fighting forces was presented to him The kit is packed with equipment essential for emergency treatment and was a gift from 500 of Dr Dattlebaum's "medical friends of Brooklyn"

Inside the black, all-metal kit was the following inscription "Presented to our brother physicians of England in honor of Maurice J Dattlebaum, M D, F A C P, president of the Medical Society of the County of Kings and Academy of Medicine of Brooklyn, N Y, U S A, by his medical friends, January 28, 1941"

BROOKLYN UROLOGICAL SOCIETY

The next meeting of the Brooklyn Urological Society will be held on Tuesday, March 11, at the Methodist Hospital, Brooklyn The scientific program is as follows 1 Case report "Carcinoma of Penis" (Motion Picture), by Dr Joseph Scialabba (by invitation), 2 Case reports "(a) Carcinoma in Ectopic Kidney," "(b) Cystectomy for Carcinoma of Bladder," by

Dr Leo S Drexler, 3 Case report "Tumor of the Ureter," by Dr Howard T Langworthy, 4. Case report "Hypernephroma of Kidney," by Dr Oscar Schoenemann, 5 "The Medical Aspects of Renal Calculi" by Dr Rosario Mulé, 6 "The Pathology of Symmetrical Cortical Necrosis of the Kidneys," by Dr Sirk A Polayes, pathologist, Cumberland Hospital

TWINS AND TORNADOES

Discussing "Insurance Against Multiple Births," the *Journal of the American Medical Association* says

"Josh Billings once said that there is one thing for which no man is ever quite prepared and that thing is twins In his time the actuaries had not given serious consideration to the incidence of multiple births Now they tell us that a plural birth occurs once in every eighty-eight pregnancies, which makes the odds reasonably certain except for the discount necessary because of the tendency toward inheritance of twinning

"Nevertheless one insurance company, perhaps as a publicity stunt, now offers indemnity for multiple births, which it calls 'plural birth insurance' For a premium of \$15 a payment of \$500 will be made, or for \$25 an 'indemnity' of \$1,000 will be paid in the event that a plural birth occurs The policy is not issued where there is record of twins on the male side Since it is now known that the roentgen ray can reveal the presence of twins in the latter half

of pregnancy, the company will not issue a policy to cover births occurring within five months subsequent to the date of the application

"So many things can happen to us nowadays that it is almost impossible to insure oneself against all of life's hazards There is the possibility of fire, earthquake, tornado, accident, soot, burglary, loss of occupation, old age, golf, war, and increased taxes There is also the possibility that the necessary premiums to protect us against all the hazards which we may meet might eventually reach our total earning power There are a number of risks that are more imminent than triplets and quadruplets Moreover, as in the case of the Dionnes, there is the possibility that multiple births might eventually be a benefit

"No doubt there are a number of prospective fathers right now who would be willing to venture a small premium if they could be given a reasonable guaranty of something happening in their lives like what the Dionne quintuplets have turned out to be"

Hospital News

Important Court Ruling on Hospital Labor Relations

A DECISION of great importance to hospitals was handed down on January 6, says *The Modern Hospital*, by the supreme court of Pennsylvania in the case of Western Pennsylvania Hospital, *et al*, vs the Pennsylvania Labor Relations Board and the Hospital Workers Local Union No 255, *et al*

Some 25 hospitals had refused to execute a proposed agreement with the unions or to negotiate any agreement and the unions then appealed to the Pennsylvania Labor Relations Board, charging unfair labor practices on the part of the hospitals. The hospitals stated that the formation of a union among hospital employees would result in demands that would jeopardize the financial ability of the hospitals to continue operation and, furthermore, that strikes or similar interruptions would jeopardize the safety of patients

The lower court granted an injunction against the state board and the unions, and this was upheld by the supreme court which stated that a hospital is not an industry nor are its employees engaged in a single trade, craft, or occupation

Health, Safety, Life at Stake

"It has not been the custom in the past to unionize hospitals," the court stated "The effect of unionization and attendant efforts to enforce demands would involve results far more sweeping and drastic than mere property rights

It is not merely a question of suspending operations, ceasing work and stopping production, such as might be true in a steel mill or automobile factory. It is a question of protecting the health, safety and, in many cases, the very lives of those persons who need the service a hospital is organized to render. The results are quite different and more extensive than are involved in an ordinary labor dispute

We cannot conceive that the legislature intended to include hospitals within the purview of the act (state labor anti-injunction act). Consequently, even though the words used might conceivably be broad enough to include a hospital, nevertheless, a hospital is not within the spirit of the act and, not being within the spirit, the act does not apply"

The court also held that the Pennsylvania Labor Relations Act did not apply because "hospitals are scientific institutions created for a humane purpose in amelioration of the sufferings of mankind." Pointing out that they require the well-coordinated services of many people, the court held that "this would be impossible, should we hold the labor act applicable with all its attending ramifications, interruptions, and possible cessation of service due to labor disputes and attending financial inability to function." The court also pointed out that the hospitals are, with few exceptions, agencies selected by the state to assist in the care of the indigent sick

The Nurse's Thoughts at 3 A M

When the wards are dark and quiet,
And the night is cool and still,
And the old neurotic patient
Has stopped yelling for a pill.
When the shaded lights are burning
By the desk and down the hall,
And the chirping of a cricket
Is the only sound at all.
Then's when you get to thinking
And you see the strangest things,
Your imagination brings
I can picture the Crimea, -
And the Lady with the Lamp,
As she valiantly trudges
On inspection round the camp;
She held a candle in her hand
And I wonder did she know
How that feeble flame she lighted
Was to multiply and grow
It brightened then a small confine,
Who was there to foresee
That later by a hundred years
The gleam would fall on me!
Whoe'er is touched is set apart
To guard a sacred trust,
To hold the light for others,
To be honorable and just
So tonight I sit and wonder
If my life will ever be
A magnifying of that flame
That came from her to me
Will I build it up and pass it on
To ever brighter grow,
Or will my influence cheapen it,
Cause it to flicker low?
May I ever do my very best
In making others see
What I can feel within my heart,
What nursing means to me.

—From *Oklahoma University News*, quoted in *Davis Nursing Survey*

Volunteer Aids in Seven Departments at New York Post-Graduate Hospital

VOLUNTEERS perform indispensable services at New York Post-Graduate Medical School and Hospital, New York City. An average of 38 volunteers are on duty each month. As told in *The Modern Hospital*, here are some of their duties in the seven departments in which they serve

Corridors and Wards—Take telephone calls, arrange flowers, check visitors on the wards, run errands for drugs and supplies, do clerical work, prepare refreshments, feed patients, make supplies, and escort patients who are being discharged

Laboratories—Make blood counts in hematology clinic and do research

Library Service—Handle the entire work, including cataloging. The library serves both patients and personnel.

Operating Room—Take telephone messages for doctors and assist in cleaning instruments

Outpatient Department—Assist the nurses, do errands, filing, typing, and admitting.

Social Service Department—Take social service histories, keep records, arrange for admissions to hospital, and do case work.

Occupational Therapy—Assist, following course of training.

Volunteers also serve at the Skin and Cancer Unit in the clinic, drug room, file room, photographic section, social service, and department of radiology.

Receptionists, or those volunteers who work on the wards and in the corridors, take a short training course. The course is repeated each month and volunteer captains serve in turn as the instructor.

Newsy Notes

Organization of 102 hospitals for the collection of surgical equipment, medical supplies, funds, and clothing to aid British hospitals is announced by the Greater New York Hospital Association.

A prefabricated, 126-bed "siege" hospital, to be shipped to England, is under construction in this country. The hospital will be operated jointly by the American Red Cross and the Harvard University public health unit. When the hospital is completed, 75 American doctors, Red Cross nurses, and laboratory technicians will make an extensive laboratory and field study of communicable diseases under wartime conditions and report their findings to the United States Army, Navy, and Public Health Service.

The National Youth Administration has approved a project for the training of forty workers in the Albany Hospital. Approximately \$5,000 will be paid these workers by the N.Y.A. According to E. W. Jones, director of the hospital, N.Y.A. workers will train as nurse aides, kitchen maids, cleaning maids, porters, office clerks, and mechanics.

Associated Hospital Service of New York now is paying hospitals at the rate of about \$8,000,000 a year for services rendered to subscribers, says Dr. S. S. Goldwater in *Hospital Reporter and Guide*.

An oxygen therapy department has been organized at Israel Zion Hospital, Brooklyn.

A blood plasma bank, to be operated by the House of the Good Samaritan and the Mercy Hospital, Watertown, has been provided through the generosity of the Watertown Lions' Club.

Patients at Meyer Memorial Hospital, Buffalo, read more than 65,000 books last year.

At a meeting of joint committees from the Tarrytown and Dobbs Ferry hospitals on February 2 it was voted to engage an architect to study both plants and advise which one would be the better for development into a hospital of 120 beds. The inference was that it might be necessary to close one hospital.

The new Triboro Tuberculosis Hospital in Queens has "musical pillows," issued on the doctor's O.K., with which the patient may enjoy radio programs without disturbing his neighbors.

St. Luke's Hospital, New York City, has a library and recreation room for employees.

Clinical photography of patients is growing so common that Dr. M. A. Weiner, of Cumberland Hospital, Brooklyn, writes a warning in *The Modern Hospital* that the legal consent of the patient must always be secured.

Dr. Edward S. Rimer has been chosen president of the society of alumni of Bellevue Hospital.

A medical staff for the Roslyn Harbor Crest Hospital has been formed of physicians on the north shore in Nassau County.

In some mental hospitals, particularly in Illinois, wards and isolation rooms are painted in a particular manner. For overactive patients, blue and certain shades of green rooms are provided in milder cases, violet and purple for the agitated and overexcited ones. Purple, by the way, is generally said to be a good soporific, though it is too strong a hue for ordinary people who want only to rest their nerves, it easily produces melancholic reactions, says Dr. J. F. Oliven in *Mental Hygiene News*.

The Rochester General Hospital news letter for December contains the statement that if all the manufacturers of instruments in this country were to work on a twenty-four hour basis it would take two years for them to produce all the instruments at present on order from the government. Not a very cheerful outlook for the hospitals and others who constantly require a new supply, remarks Editor Ponton of *Hospital Management*.

Improvements

Riverside Hospital, on North Brother Island in East River, is to be enlarged by a three-story building for tuberculous patients. Costing

\$1,103,350, it will occupy a site 360 by 150 feet, have 152 beds, and serve as the entire hospital's administrative and surgical center

A campaign is to be launched to provide a new public hospital at Massena

A \$50,000 addition to the Julia L. Butterfield Memorial Hospital at Cold Spring is contemplated

An addition to the Oneida City Hospital is being advocated to provide twenty-five more beds

The superintendent of Ilion Hospital, Miss Ruth Yale, declares in her annual report that the present plant is inadequate and asks for an enlargement

Knickerbocker Hospital, Manhattan, has a new x-ray department

A new x-ray machine and equipment have been given to Our Lady of Victory Hospital, Lackawanna, by American Legion Post 63

A \$1,700 iron lung has been presented to Columbus Hospital, New York City, by the Isaac Gimbel Memorial Post 1206, American Legion

KEEP THE PROFESSION OUT OF THE MINUS COLUMN

Dr. Alfred M. Hellman, new president of the Medical Society of the County of New York, in his inaugural address on January 27, pointed to the decline in German medicine as a warning against government-controlled medicine in this country.

"In Germany," he said, "medicine is taking a decided backward step under totalitarian rule and placing the health of its people in the hands of only partially trained medicos."

He then turned to conditions in the medical profession here and said it was true that some physicians in this country had found it difficult to earn enough to support their families and to educate their children, and they felt as a result that "any change would be an improvement," but he asserted vigorously that this was "a view which I definitely do not share."

"No matter what smaller temporary gains would come to a few physicians under government-controlled medicine," he asserted, "the net result to the medical profession would be in the minus column."

"The larger the sum voted by the federal or state government for medical care, the greater would be the number of nonmedical people living from this liberal donation, the greater would be the stranglehold on the medical profession and the kind of medicine it could practice."

Dr. Hellman said he had tried to visualize what would happen to his younger colleagues under suggested changes involving the government in medicine.

"Only the few with little practices and those with political influence would gain advantage,"

he declared. "A few incompetent or unfortunate physicians might be lifted by the bootstraps and momentarily raised from their mire of discontent, but this at the expense of the vast majority."

Referring to his inauguration at the meeting as head of the organization of more than 5,000 physicians, Dr. Hellman said he disliked being tagged with the label "conservative, with the meaning certain of our doctors have placed on it," but he said he deserved that name if conservatism meant "being against Communism, and against state-controlled medicine run by lay people."

Scanning the local medical picture, he told his fellow physicians that one recent development which needed watching was "nonprofit sickness insurance." Too many companies for this purpose are being formed, he said.

Regulations also would be needed to keep the increasing partnerships and cooperatives of physicians "in line with our views of democracy, fair competition, and free choice of physician," he said.

Dr. Hellman also told reporters in an interview that he had appointed a committee of seven to work out a plan by which the plasma method of preserving blood, now being used to send blood to Great Britain, could be used to provide adequate quantities of plasma for indigent patients in local hospitals too small to maintain one of the so-called blood-banks. He said it was hoped that this program could be worked out by the end of this year.

"IF IT COMES"

"If It Comes," Greater New York will not be caught napping, says the *New York Medical Week*. The first meeting of Mayor LaGuardia's City Defense Council revealed that the Administration has already gone a long way toward

planning emergency measures should they ever be necessary. Police and fire precautions have been mapped. It remains to perfect details, enlist volunteer aides, and teach the public how to meet various dangers calmly and intelligently.

Public Health News

Revision of Clinical Aspects of Pneumococcus Pneumonia

SECTION 3 of the loose-leaf handbook, *Clinical Aspects of Pneumococcus Pneumonia*, issued by the Bureau of Pneumonia Control of the Division of Communicable Diseases has just been completely revised. It summarizes the recent advances in the specific treatment of pneumonia, with particular reference to chemotherapy and antipneumococcus serum, and attempts to incorporate the consensus of the following authorities who have assisted in the revision: Doctors Jesse G M Bullock, Russell L Cecil, Lloyd D Felton, Maxwell Finland, Colin MacLeod, Norman Plummer, and the medical staff of the Bureau of Pneumonia Control.

The new section should be substituted for Section 3 of the original loose-leaf handbook issued early in the fall of 1939. A copy of the re-

vision has already been sent to physicians who requested the handbook in answer to a questionnaire sent out in the summer of 1939. Unless the Department has been notified of any subsequent change of address, the revision has been mailed to the address given at that time.

Physicians located in New York State, outside of New York City, who did not request the handbook when it was first published may obtain it on request to the Bureau of Pneumonia Control, State Department of Health, Albany, New York. This publication is available only to registered doctors of medicine and to osteopaths authorized to use biologic products under the provisions of Chapter 741, Laws of 1939. The New York City Department of Health supplies a similar manual for physicians practicing in New York City.

Postgraduate Lecture Courses

Dr Clayton W Greene, Buffalo University College of Medicine, has arranged a course on the Treatment of Common Diseases for the Schenectady County Society to be held in Schenectady, at 4 30 p.m. The schedule of talks is as follows: March 5, "Treatment of Common Skin Lesions," by Dr Earl D Osborne, March 12, "Treatment of Epigastric Distress Following Meals," by Dr A. H. Aaron, March 19, "Treatment of Dyspnea," by Dr Frederick T Schnatz, March 26, "Treatment of Precordial Pain," by Dr Clayton W Greene, April 2, "Results of Modern Methods in the Treatment of Anemia," by Dr Francis D Leopold, March 9, "Treatment of Low Back Pain," by Dr Frank H Potts, all of Buffalo.

A course of lectures on General Medicine, arranged for Wayne County Society, is being held in Newark and Lyons, alternately. Included in the series are the following lectures: On February 4, "Goitre—Its Management," by Dr Frederick S Wetherell, Syracuse, February 18, "Treatment of Chronic Rheumatism," by Dr Russell L Cecil, New York City, March 4, "Carcinoma of the Female Genitalia," by Dr Nathan P Sears, Syracuse, March 18, "What Can We Do for Angina Pectoris and Coronary Occlusion?" by Dr Clayton W Greene, Buffalo, April 1, "Recent Advances in Obstetrics," by Dr James K Quigley, Rochester, April 15, "Staphylococcal Disease," by Dr O W H Mitchell, Syracuse.

The lectures on "Carcinoma of the Female Genitalia" and "Recent Advances in Obstetrics" are given in cooperation with the State Department of Health.

A course on General Medicine, arranged for Genesee County Society and held at Batavia at 8 30 p.m., is as follows: February 18, "Treatment of Chronic Rheumatism," by Dr Russell L Cecil, New York City, March 4, "Carcinoma of the Female Genitalia," by Dr Nathan P Sears, Syracuse, March 18, "What Can We Do for Angina Pectoris and Coronary Occlusion?" by Dr Clayton W Greene, Buffalo, April 1, "Goitre—Its Management," by Dr Frederick S Wetherell, Syracuse, March 15, "Staphylococcal Disease," by Dr O W H Mitchell, Syracuse, May 6, "Recent Advances in Obstetrics," by Dr James K Quigley, Rochester.

Dr A. F. R. Andresen, Long Island College of Medicine, Brooklyn, has arranged the following course on General Medicine for the Otsego County Medical Society, to be held at Oneonta, at 8 30 p.m.: March 12, "Dietary Therapy in Gastrointestinal Disease," by Dr Albert F. R. Andresen, April 9, "The Diabetic Patient and the General Practitioner," by Dr Milton B Handelsman, May 14, a subject in obstetrics, to be decided later, by Dr Mervin B Armstrong, June 11, "Some Problems in Cardiac Diagnosis," by Dr J Hamilton Crawford, all of Brooklyn.

SPECIAL LECTURE

The New York Polyclinic Medical School and Hospital wishes to announce a special lecture by Dr Russell L Cecil, professor of internal medi-

cine, New York Polyclinic Medical School and Hospital, on Wednesday, March 26, on "The Present Status of the Theory of Focal Infection."

Woman's Auxiliary

To the Medical Society of the State of New York

DR. JAMES M. FLYNN, president of the Medical Society of the State of New York, sends our members this message. "As you must know, the Medical Society of the State of New York is divided into eight district branches embracing in all sixty-one county societies. Thus, the district meeting is an important event which merits the interest of all members of the component groups. In my visits to the different district meetings, I was most favorably impressed by the meeting of the second branch held at Mitchel Field, as well as by that of the eighth held at Niagara Falls. Both of these meetings left little to be desired either in respect to attendance or interest shown. And credit for this happy result must certainly be given to the woman's auxiliaries of these district groups. To my mind, the whole-hearted cooperation of the women in the varied activities incident to the meetings was largely responsible for their success. The work of the physicians' wives at these gatherings has a particular value, and it calls for commendation and encouragement. I would urge the formation of more auxiliaries and suggest that a real effort be made to enlist the support of all physicians' wives, to the end that the district meetings be accorded the response that their importance would seem to demand. Further, may I state that the contribution of the woman's auxiliaries to organized medicine need not stop at this point. Their interest gives rise to the hope that they may become an effective force in bringing to the community at large a more intelligent understanding and appreciation of the ideals and objectives of the medical profession."

The midwinter executive board meeting of the State Auxiliary was held at the DeWitt Clinton Hotel, Albany, on February 5. Mrs. Luther H. Rice graciously presiding. Informative reports of the standing committees were read. Their fine work is highly commendable. Of special interest was the accomplishment by the Physicians' Home Committee. Inspiring reports of county presidents were read by Mrs. A. L. Madden, Albany, Mrs. J. Roberts, Broome, Mrs. C. E. Wertz, Erie, Mrs. O. J. Mowry, Herkimer, Mrs. L. Harris, Kings, Mrs. S. L. Homrighouse, Montgomery, Mrs. W. R. Scott, Niagara, Mrs. J. I. Farrell, Oneida, Mrs. E. M. Neptune, Onondaga, Mrs. W. W. Davis, Orange, Mrs. J. Rainey, Rensselaer, Mrs. T. Bullard, Saratoga, Mrs. A. W. Greene, Schenectady, Mrs. W. C. Carhart, Suffolk, Mrs. I. V. Decker, Washington. Dr. Joseph Lawrence addressed the group and emphasized the importance of medical legislation. He also extended the members an invitation to visit the legislative sessions. Mrs. Carlton Potter, Syracuse, member of the national board, reported her attendance at a meeting of the public relations committee. She advocated that all doctors' wives acquaint themselves with current movies, plays, and books pertaining to medicine. Those who attended,

in addition to county presidents, were Mesdames George B. Adams, president-elect, H. J. Noerling, J. E. Noll, C. Potter, F. Irving, E. A. Griffin, G. Towne, W. J. Lavell, L. A. VanKleeck, O. Pfaff, J. P. Lasho, A. Vander Veer, R. F. Johnson, F. L. Sullivan, S. P. Jones, and A. M. Bell. The fifth anniversary of the organization of the State Auxiliary was celebrated by a dinner and a get-together party February 4 at the DeWitt Clinton Hotel.

County News

Erie The executive board and assistants to the chairman of the state convention were delightfully entertained at dinner by Mrs. C. E. Wertz, chairman of the convention. All plans were formulated and discussed. The committee is putting every effort toward making this event an outstanding affair.

Onondaga The regular monthly meeting of the Auxiliary was held at the Crouse Irving Hospital on Tuesday evening, February 4, forty-eight members being present. Dr. C. George Murdock spoke on "Health Tests for Household Workers." Interesting points on current legislation were also presented by Mrs. E. G. Allen, legislative chairman, for general discussion in the meeting. Plans for a birthday dinner-dance were presented in detail before the meeting by Mrs. Glendon R. Lewis. The party was held February 13, at the University Club of Syracuse. It was a formal affair and a buffet dinner was served. The committee on public relations directed a collection of surgical instruments, sedatives, vitamins, and baby foods for Britain.

Oswego Social comradeship among members of the medical profession and their wives was held by giving a dinner-dance at the Hotel Pontiac on December 13. The occasion afforded so much pleasure that it was agreed to hold an Easter dinner-dance party. An annual Christmas gift of hospital scales was made to the County Health Camp. Dr. Joseph M. Riley gave an interesting talk on the subject "Juvenile Eyesight" at the regular monthly meeting on January 8. This county reports their membership as being very enthusiastic about auxiliary work.

Schenectady Mrs. Walter Drew, president of the Public Health Nursing Association, spoke on the relation of the medical profession to her work at the regular monthly meeting held at Sunnyview Hospital, January 28. The requirements of public health nurses and their duties were explained. At the business meeting Mrs. A. W. Greene, president, announced that all members were being classified for medical defense work. A social hour and tea followed.

Suffolk A luncheon and executive board meeting, at which Mrs. W. C. Carhart presided, was held January 4, at the Milestone Inn, Sayville, Long Island. The group formulated plans for the coming year. A dinner party, with the doctors as guests, was given at the Patchogue

Hotel on January 29 The following officers are carrying on the active work for this year—president, Mrs W C Carhart, president-elect, Mrs George P Bergman, Mattituck, first vice-president, Mrs S A Arnold, Bay Shore, second vice-president, Mrs L P Gouley, Huntington, recording secretary, Mrs A. Franklin, Central Islip, corresponding secretary, Mrs B Feurstein, Bay Shore, treasurer, Mrs W R. Carman, Islip, delegates to the State Medical Convention are Mrs Bergman and Mrs Gouley, alternates, Mrs Kolk and Mrs Jones. Directors are Mrs Frank Overton, of Patchogue, and Mrs E R. Hildreth, of Bay Shore.

Convention

Come all ye sisters—pack your duffel and shuffle off to Buffalo on April 28, for the convention time of your life. This is to be a convention that is different! The extracurricula activities will appeal to you. The regulation teas, luncheons, and banquets will be in order but with at-

mosphere. Aside from that, Buffalo, "The City of Good Neighbors," offers you hospitality to rival the sunny southland. The Niagara Frontier in the pioneer spirit of "Wells Fargo Days" bids you come and twist the Buffalo tail. Breathes there a girl with soul so dead who doesn't evince some flickering of interest in her house? The Niagara Frontier abounds in antiques and antique shops. This is a collector's paradise. The finest rock crystal in the country is manufactured in Buffalo. Wouldn't you like to see how? Buffalo's parks and museums will be a treat to the lovers of beauty among you who are artistically inclined. Buffalo in the Spring—well—what matter the weather as long as we're together—Mrs C E Wertz, convention chairman.

Bulletin

Our goal for the Bulletin is 350—we have 103 to date. Send your subscription to your county chairman today!

THE HIT CHIROPRATIC BIRD FLUTTERS

"Chiropractic is a distorted technic for the diagnosis and healing of disease, which is being foisted on the American people, notwithstanding that its advocates lack the slightest conception, let alone appreciation, of the most elementary and clearly demonstrable facts in connection with the human body in health and disease," the *Journal of the American Medical Association* for February 1 says in an editorial on "The Chiropractic Theory of Law."

The editorial continues: "The realities of anatomy, pathology (the essential nature of disease), physiology, and chemistry mean nothing to chiropractors. Nevertheless, any informed person who points out the inanity of their theories and the baneful effects of their treatment is, by their propaganda, bigoted, hidebound, reactionary."

"Chiropractors are in general quite uninformed in the field in which they hold themselves out as having some knowledge or aptitude. When they digress into other fields, they usually reveal such appalling ignorance that even the most casual observers see them in their true light. Few people realize that chiropractors, unlike physicians, seldom if ever have any college education, indeed, some have not even completed the high school. In the *National Chiropractic News* for November-December, 1940, appears an editorial entitled 'Witch-Hunting in Indiana.' This rumination was elicited in response to what appears to be a campaign of T M Overley, secretary of the Indianapolis Better Business Bureau, looking toward the prosecution under the laws of the state of Indiana of all unlicensed chiropractors practicing in the state. These individuals seek to practice in disregard of such an inconvenient and inconsequential technicality as obtaining a license after presenting to the Board of Registration in Medicine evidence of the educational qualifications required by the Medical Practice Act of Indiana and satisfactorily passing the

examination required by law. Mr Overley, so the editorial states, is 'bluenosed' in this campaign 'against qualified but unlicensed chiropractors.' Were this statement not so pathetic, it would be ludicrous. 'Qualified' by whom, for what? Shall cultists be permitted to ignore the applicable healing art licensing law if, in their own estimation, they possess the qualifications required by that law? Is the matter of licensure not a function of the state?

"Quoting directly from the editorial 'We asked him [the secretary of the Indianapolis Better Business Bureau] to distinguish and differentiate between the qualified, responsible [unlicensed] practitioner and the unqualified racketeer'."

"Granting, without admitting, that such a distinction could be drawn, the request for such a distinction itself evidences the unique mentality behind chiropractic thinking. Apparently it is good chiropractic theory to ignore a healing art licensing law on the ground that such a law applies to the mass of men and to physicians but not to any adherent of this blissfully uninformed cult."

"Mr Overley, because of this campaign against all chiropractors violating the licensing laws of the state, because of his 'purblind, bigoted' refusal to take the heat off 'qualified but unlicensed chiropractors,' is, the editorial remarks (after giving due credit to General Hugh Johnson for originating the phrase), 'suffering from halitosis of the intellect.' This significant diagnosis, notwithstanding its origin in the General and its acceptance by the chiropractors, is just as scientific as chiropractic itself. The editorial implies that Mr Overley's efforts to suppress the unlicensed practice of chiropractic must be bearing some fruit. However unfortunate from the chiropractic point of view, this consummation is distinctly in the public interest."

Books

Books for review should be sent to the Book Review Department at 1313 Bedford Avenue Brooklyn, N. Y. Acknowledgment of receipt will be made in these columns and deemed sufficient notification. Selection for review will be based on merit and interest to our readers

REVIEWED

Sexual Pathology A Study of Derangements of the Sexual Instinct By Magnus Hirschfeld, M.D. Octavo of 368 pages New York, Emerson Books, Inc., 1940 Cloth, \$2.95

Sexual Pathology is a comprehensive, detailed study of the derangements of the sexual instinct. In the three main divisions into which the volume is divided (Sexual Symbolism, Hypereroticism, and Impotence), the author, with the aid of case histories, analyzes the many sexual abnormalities.

It is chiefly a dissertation on the various sexual idiosyncrasies. Therapy, which would have been helpful to those interested in the problem, is but superficially discussed and then only in rare instances.

Although its direct, easy flowing style and the vivid account of cases would be very enlightening and interesting to the layman, the frank discussion of such subject matter naturally warrants restricting the book to members of the medical profession or advanced students of psychology.

SAMUEL L. SIEGLER

Clinical Diabetes Mellitus and Hyperinsulinism. By Russell M. Wilder, M.D. Octavo of 459 pages, illustrated Philadelphia, W. B. Saunders Co., 1940 Cloth, \$6.00.

There is a very definite need for this type of work on the subject of diabetes mellitus (and the reviewer welcomes the inclusion of the clinical opposite hyperinsulinism) that may be recommended as a text on these subjects to medical students and general practitioners.

The book is not a collection and revision of a great mass of reference material and, as is too often the case in this type of subject, an accumulation of statistical data. Dr. Wilder covers the essentials necessary for clinical application of these diseases and presents them practically.

The method of using footnotes throughout the text is to be commended, and it is hoped that this style of presentation will become more popular in future medical texts.

Of great importance is the stress put on having the diabetic diet meet all nutritional requirements of proteins, minerals, and vitamins. Many workers in the field of diabetes mellitus will not agree with Dr. Wilder on the relatively high caloric values of his diet prescriptions due to the generous use of fats. The food lists are given in composition of 100-Gm. portions which complicates diet calculation by the physician and the patient and adds the burden of the use of scales, which in this country is gradually being displaced by the use of household measure.

The management of diabetic coma, the surgical diabetic, and the regulation with insulin are particularly well presented. The section on hyperinsulinism is well done and presented in a completely practical manner for direct clinical approach.

This book is highly recommended as a text for students and general practitioners.

PAUL C. ESCHWEILER

The Diagnosis and Treatment of Diseases of the Peripheral Arteries By Saul S. Samuels, M.D. Second edition. Octavo of 372 pages, illustrated New York, Oxford University Press, 1940 Cloth, \$6.50.

Although the author has completely rewritten this edition, he has added very little to what was already presented in the first edition. The only noticeable difference appears to be that instead of devoting three-fourths of his book to thromboangitis obliterans he now devotes one-half of the book to this subject. This is done in spite of the fact that thromboangitis obliterans is a relatively rare disease and makes up about 5 per cent of the total incidence of peripheral arterial diseases. The clinical and pathologic description of Buerger's disease is good. The value of intravenous hypertonic saline in treatment is extolled while all other methods are deprecated. His treatment of the subject of arteriosclerosis obliterans is poor, inadequate, and confusing. He presents a total of ten illustrated case reports of diabetic gangrene in this chapter. Nine out of the 10 are cases of acute, infectious, diabetic gangrene, which from the textual matter are obviously cases with patent major arteries. This is disclosed by oscillographic readings in these cases ranging between one-half and eleven at the ankle. These 9 cases without arterial impairment got well with good local surgical management. The only 1 that came to mid-thigh amputation in his series had an oscillographic reading of zero. Thus he presents successful results, in the chapter on arteriosclerosis obliterans, in patients who did not suffer from arteriosclerosis obliterans at all. This is misleading. What is equally important if not most important in this group is infarctive gangrene due to arterial impairment. This the author completely ignores. In the conservative treatment of obliterative arteriosclerosis as well as in Raynaud's disease, he recommends, for some mysterious reason, the use of intravenous hypertonic saline.

W. S. COLLENS

New Facts on Mental Disorders Study of 89,190 Cases By Neil A. Dayton, M.D. Octavo of 486 pages, illustrated. Springfield, Charles C. Thomas, 1940 Cloth, \$4.50.

This is an epochal book. It embraces a commendable analysis of 90,000 admissions to mental hospitals in Massachusetts from 1917 to 1933.

Dr. Dayton, with an able group of advisors, has made possible the answers to inquiries, such as: Why a yearly increase in admission rate? What are the modifiable factors? In significant language that no physician, sociologist, or intelligent layman should fail to comprehend.

Unlike many books that are dominantly statistical in content, the present one is happily readable. The gist of each chapter may be quickly gleaned by virtue of a pithily formulated summation which precedes each of eleven topical groupings. These include general considerations, age

in mental disorders, nativity, alcohol, marriage, age, time, other clinical factors, and a penetrating discussion of factors influencing the incidence of mental disorders

The book is replete with graphs which strikingly and concisely bring to the front the upshots of this much needed study

FREDERICK L PATRY

Rheumatic Fever Studies of the Epidemiology, Manifestations, Diagnosis, and Treatment of the Disease During the First Three Decades By May G Wilson, M D Quarto of 595 pages, illustrated New York, Commonwealth Fund, 1940 Cloth, \$4.50

Dr Wilson's excellent monograph will take its place at once as the standard work in its field and one of the most important in any field The author disclaims any attempt at encyclopedic treatment of the subject, yet the volume is so comprehensive that it is unlikely that search here for any important data on rheumatic fever would be fruitless

There are 578 pages, a good index, and a bibliography It is subdivided into five parts: epidemiology and etiology, clinical and pathologic manifestations, course, diagnosis, and care and management There are invaluable appendices containing miscellaneous supplementary material, such as tables analyzing 112 rheumatic families, technic of tests used in studying rheumatic fever, nomenclature and criteria for diagnosis of diseases of the heart of the New York Heart Association, etc This book, like other Commonwealth Fund publications, is beautifully bound and printed and is very reasonably priced

MILTON PLOTZ

Treatment of War Wounds and Fractures With Special Reference to the Closed Method as Used in the War in Spain By J Trueta, M D Duodecimo of 146 pages, illustrated New York, Paul B Hoeber, Inc, 1940 Cloth, \$2.50

This interesting little monograph is the story of the treatment of compound fractures during the recent civil war in Spain

After a brief historical survey of war surgery, the author gives a lucid description of the treatment and explains the principles on which it is based Then follow several chapters in which fractures of various bones are considered individually

The method of treatment is that introduced by Dr Winett Orr some sixteen years ago The results obtained prove the contention that closed plaster immobilization is the *sine qua non* in the treatment of compound fractures

MAYER E ROSS

Manual of Medical and Surgical Emergencies Edited by J C Geiger, M D Octavo of 199 pages San Francisco, J W Stacey, Inc, 1940 Cloth, \$2.50

The most suitable description of this book is that it is eminently sensible Almost every conceivable emergency likely to be encountered in this part of the world is adequately treated. One defect is that there is no section on poisons since toxicology is covered in a companion volume A chapter on the common poisons would make this volume a complete unit

MILTON PLOTZ

Behind the Scenes of Murder By Joseph Catton, M D Octavo of 355 pages New York, W W Norton & Company, 1940 Cloth, \$3.00

This book makes interesting and instructive reading for doctors, laymen, and lawyers It is not a collection of murder mysteries by a doctor but an attempt at the interpretation of the crime of homicide as seen through the experiences, in and out of court, of a distinguished psychiatrist He has evidently examined many murderers, and he analyzes their cases first as an alienist, but an alienist with the inquisitiveness of a sociologist and the thoughtful citizen. Are all the verdicts just or adequate? The doctor feels that, in spite of laws, human nature pulls the strings at some time or another for the judge, the attorneys, the experts, and the juries The chapter on "The Insanity Dodge" is illuminating and includes the statement "My and the jury's opinion in 84 per cent of the cases of killers' alleged insanity was that the insanity defense was an insanity dodge" One of the concluding chapters deals with the prevention of homicide Here will be found some vital observations and conclusions of a student of crime and crime prevention Whether he agrees or not with the opinions expressed, the casual reader will be deeply impressed by the seriousness of the problems outlined

JOSEPH RAPHAEL

Physiology of Micturition By Orthello R. Langworthy, Lawrence C Kolb, and Lloyd G Lewis Octavo of 232 pages, illustrated Baltimore, Williams & Wilkins Co, 1940 Cloth, \$3.50

Within the pages of this compact and scientific treatise are contained valuable contributions to the study of the neuromuscular disturbances of the bladder It is the type of book which may be used as a consulting reference not only by urologists and neurosurgeons but by the general profession as well A large amount of experimental and clinical research have formed the basis of the concise and factual data contained therein. An extensive bibliography of the more important references is appended, as well as an alphabetical authors' index One cannot praise too highly the efforts of the authors for their experimental, clinical, and cystometric studies made possible financially by grants from several philanthropic organizations. The open-minded manner in which they have approached and studied the mechanism of micturition, together with the lesions produced by disease and injury of the brain, spinal cord, and various peripheral nerve structures, is most commendable The text is conveniently arranged in six separate divisions

AUGUSTUS HARRIS

Artificial Pneumothorax Its Practical Application in the Treatment of Pulmonary Tuberculosis Contributions by Saranao Lake Physicians to the Studies of the Trudeau Foundation Editorial Committee Edward N Packard, M D, John N Hayes, M D, Sidney F Blanchet, M D Octavo of 300 pages, illustrated Philadelphia, Lea & Febiger, 1940 Cloth, \$4.00

Here in a small volume is a complete presentation of all that is of value on the subject of artificial pneumothorax in the treatment of pulmonary tuberculosis Some seventeen of the physi-

cians resident in Saranac Lake have aided in its production, each contributing a chapter or two, according to his special fitness, without loss of continuity in thought. There are nineteen chapters running from a historical review of the subject through the physiology of artificial pneumothorax, the selection of cases, the value of the x-ray in following the cases, a description of the apparatus employed, the technic of the procedure, accidents that may occur during the operation, pleural complications that may occur, etc., and end results of the treatment. It is all exceedingly well done and bears the mark of conservatism which as a rule characterizes the Saranac School.

The volume is beautifully illustrated, extremely well documented, and attractively presented. All students of pulmonary tuberculosis will find it a valuable addition to their libraries.

FOSTER MURRAY

Acute Infectious Diseases. A Handbook for Practitioners and Students. By J D Rolleston, M D, and G W Ronaldson, M D. Third edition. Octavo of 477 pages. St Louis, C V Mosby Company, 1940. Cloth, \$4.50.

Dr Rolleston's book has been a standard and authoritative text on the clinical aspects of acute infectious diseases ever since the first edition was published. Based on the writer's extensive personal experience in this field and on a most careful study of the literature, this publication has, since its first appearance, maintained a leading position. In this new edition the authors have added to its authoritative position by a most thorough revision, with presentation in an excellent manner of the modern views on the questions of diagnosis and treatment in conjunction with concise descriptions of the clinical picture and the bacterologic and pathologic aspect of each infection. The diseases included are those that are usually treated in isolation hospitals and include the usual exanthemas, diphtheria, mumps, whooping cough, typhoid, paratyphoid and typhus fever, cerebrospinal fever, the fourth disease, erythema infectiosum, with chapters on vaccination, Vincent's angina, erysipelas, and isolation methods. The book is quite up to date. The opinions expressed are the result of thorough familiarity with the subject matter, and they are most logical and certainly reliable and conservative. Many subjects of much current interest are discussed, and of particular importance may be mentioned the suction method for treatment of laryngeal diphtheria, the use of various prophylactics for measles including convalescent serum and placental globulin, the antitoxin therapy of scarlet fever, the drip infusion method of serum therapy, and the place of chemotherapy in certain of the acute infectious diseases. This book will provide the practitioner and the health officer with a valuable and reliable source of information on the modern management and treatment of this group of communicable diseases.

JOSEPH C REGAN

The Surgery of Pain. By René Leriche, M D. Translated and edited by Archibald Young, M D. Octavo of 512 pages, illustrated. Baltimore, Williams & Wilkins Co., 1939. Cloth, \$6.50.

The work of Leriche, especially the operation of penarterial sympathectomy devised by him

and employed in the treatment of a variety of disorders of the extremities, is a contribution quite generally known. There are, however, many other problems that have attracted the attention of this careful clinical investigator—to mention a few neuralgias of the face, causalgia, the pain of amputation stumps, Raynaud's disease and the pain of angina pectoris. This book is written in a simple straightforward, easily understood style, recounting some experiences that have been previously recorded but with bringing up to date our knowledge concerning the results that may be obtained in the relief of pain by surgical measures. The treatise has the touch of the master, René Leriche, who has been most responsible for the advances made in the treatment of a large number of painful disorders by appropriately applied operations on the sympathetic nervous system. It is highly recommended to all, for in the reviewer's opinion it will be found far more entertaining than many of the biographies now appearing on the bookshelves.

JEFFERSON BROWDER

Diseases of the Nervous System. By W Russell Brain, M A. Second edition. New York, Oxford University Press, 1940. Cloth, \$9.25.

The first edition was published in 1933 and on the whole was well received. As stated at the time it possessed the particular quality of unusual clarity so that each syndrome read as if chiseled in stone. Seven years have elapsed during which period newer concepts of disease, further refinement in diagnosis, and distinct therapeutic advances have occurred. On all these phases practically new chapters have been written.

There also has been a new arrangement of material, such as placing all diseases caused by virus infection under one heading. A separate chapter has been reserved for syphilis. The chapters on endocrine and trophic diseases have been omitted, which is unfortunate.

The number of illustrations, 79, seems adequate for this type of book. It is recommended particularly for senior medical students.

HAROLD R. MERWARTH

Dermatologic Therapy in General Practice. By Marion B Sulzberger, M D, and Jack Wolf, M D. Octavo of 680 pages, illustrated. Chicago, The Year Book Publishers, 1940. Cloth, \$4.50.

As a collaborator in the production of the annual *Yearbook on Dermatology and Syphilology* with Dr Fred Wise and author of the recently published and most instructive book on dermatologic allergy, this new work should need but little introduction to the general practitioner to whom he seems to dedicate it so modestly in his title. It might well have been called a handbook for the dermatologist, for it contains much that any practitioner of our branch of the art of medicine could read with distinct advantage. One of the weak spots in many of the authoritative works on dermatology is the paucity of descriptive instruction concerning the proper and most advanced methods of therapy and the actual application of the same. This sort of knowledge and technic is the result of long clinical training which every aspiring dermatologist must pursue before he may call himself a specialist in his field. The book is a perfect *vade mecum* of

dermatologic information Not only are the descriptions of various diseases of the skin clearly defined in the text but series of pictures are given which are certain to aid the reader in the differentiation of diseases similar in their objective symptoms Lucidly described and generously illustrated are the methods for the preparation and application of various dressings, ointments, pastes, patch-testings procedures, and parenteral therapy Formulas that have served faithfully for many years, as well as those of recent invention, are given in profusion The chapter on the proper treatment of acne in its various stages is very instructive, and the advice offered for passing along to the patients is most sensible and valuable

NATHAN THOMAS BEERS

Communicable Diseases By Nina D Gage, R N, and John F Landon, M D Second edition Octavo of 411 pages, illustrated Philadelphia, F A. Davis Company, 1940 Cloth, \$3 50

This second edition is a clear, concise, comprehensive textbook covering all the important features of the common contagious diseases, written with a view toward the teaching of nurses Nursing care of each disease is given in a separate chapter following the disease Some other valuable additions are a glossary to clarify technical terms, a schematic representation of the discussion of each disease at the beginning of the chapter detailing each disease, and questions at the end of each chapter which if answered by the student will fix the principal points in mind The book should be helpful to the medical student The newer chemotherapeutic methods are included

KENNETH G JENNINGS

Clinical Methods A Guide to the Practical Study of Medicine By Sir Robert Hutchison, M D, and Donald Hunter, M D Eleventh edition. 16 mo of 622 pages, illustrated New York, Paul B Hoeber, Inc., 1940 Cloth, \$5 00

The eleventh edition of this well-known work is a handy collection of the various clinical methods used in diagnosis and treatment Although it consists of 622 pages, it is small enough to be carried in a pocket for easy reference This edition represents a well-written volume, with many deletions of old material and additions of new It should prove to be a valuable help to the practicing physician

MAX LEDERER

A Synopsis of Surgery By Ernest W Hey Groves, M D Eleventh edition. Duodecimo of 714 pages, illustrated Baltimore, Williams & Wilkins Co., 1940 Cloth, \$5 00

This small volume which has been, since its first edition in 1908, a brief summary of surgical procedures is a popular desk volume, and the present edition, as were its twelve previous editions, has been brought up to date This is particularly true of the sections on the treatment of fractures and the section on cleft palate In these the text for the most part has been rewritten, with the recent work of Veau included and the operative procedures of Langenbeck, Lane, and Brophy omitted

It will undoubtedly be regretted by some that the chapters in the previous editions on regional

diagnosis have been deleted The reviewer, for one, has always thought that they gave the volume something that made it more readily a desk reference book The arrangement of the subject matter is essentially the same as in the previous editions in that there is a brief discussion of etiology, pathology, complications, and treatment Affections of the entire body with the exception of the female genitalia are considered The illustrations are for the most part black and white but well done

HERBERT T WIKLE

Essentials of the Diagnostic Examination. By John B Youmans, M D Duodecimo of 417 pages, illustrated New York, The Commonwealth Fund, 1940 Cloth, \$3 00

This handbook will be of considerable help to medical students and to practitioners who wish a concise reference book on the problems of diagnostic examination There is no material in the book which is not to be found in similar works now available However, the Commonwealth Fund is to be commended for making a readable and dependable text available at so low a price The sections on office laboratory procedures and cardiac and neurologic examinations are especially good

MILTON PLOTZ

Bailey's Textbook of Histology By Philip E. Smith, Ph D, editor, and others Tenth edition Octavo of 764 pages, illustrated. Baltimore, Williams & Wilkins Co., 1940 Cloth, \$6 00

Again the authors have compiled a text in this tenth edition which should benefit the student and teacher alike Numerous illustrations and sketches make for a clear and concise explanation of the subject matter

Two new chapters have been added one of these is on morphogenesis, and the other on the organization of nervous tissues A short list of references has been added to each chapter

This volume should be an aid to students of medicine

NATHAN REIBSTEIN

Getting Ready to Be a Mother By Carolyn C Van Blarcom Fourth edition revised by Hazel Corbin Duodecimo of 190 pages, illustrated New York, The Macmillan Company, 1940 Cloth, \$2 50

Written in a clear understandable style and profusely illustrated, this little volume makes a satisfactory instruction manual for first-mothers Prenatal care, nutrition, and postpartum exercises are intelligently handled

JAMES F BUTLER

The Fundamentals of Nutrition By Estelle E Hawley, Ph.D., and Esther E Maurer-Mast, M D Including Table of 100-Calorie Portions by Estelle E Hawley, Esther E Maurer, and Herbert F Van Epps, and Discussions of the Dietary Management in Specific Conditions by collaborators associated or formerly associated with the University of Rochester, School of Medicine and Dentistry Quarto of 477 pages, illustrated Springfield, Charles C Thomas, 1940 Cloth, \$5 00

This book goes straight to the point. It tells the physician what he should know about the fundamentals of nutrition, diet therapy, and diet planning. All the information and data are strictly relevant, historical and laboratory background is kept at a minimum.

The book is clearly written and illustrated with meaningful charts and pictures. Each chapter in the diet therapy section is written by a specialist in his field. The approach is always direct and practical. The physician learns not only what to prescribe, but—and this is just as important—how to prescribe it. Stress is laid on diets as modifications from the normal family meals rather than as separate entities. Consideration is given to the economic factors in diet teaching and diet planning which affect the largest majority of our population today.

The volume concludes with a liberal appendix, including a 100-calorie table, a section on evaluation of nutritional status, commercial vitamin products, some recipes and food suggestions for special conditions, and special diet instruction sheets.

This book is highly recommended for reference and everyday use because of its technical value and its fresh and practical point of view.

ETHEL PLOTZ BERMAN

Introduction to Medical Biometry and Statistics. By Raymond Pearl. Third edition. Octavo of 537 pages, illustrated. Philadelphia, W B Saunders Co., 1940. Cloth, \$7.00.

This is not an elementary textbook on statistical methods, proceeding from first principles through mathematical development to practical application, but is essentially a survey of the working methods most popular among American and British medical biometricians and statisticians. This assortment of working methods is well covered, and each process is illustrated with an analysis of data drawn from a field interesting to medical men. These illustrations are given in such detail that the numerical processes involved can be followed step by step. The reader is given a prolonged glance over the author's shoulder (Professor Pearl is an active worker in the field of medical biometry and statistics) and obtains a very definite idea of the kind of data he works with and how he analyzes this data. But not much is given as to the epistemology of mathematical statistics, or about the alternative methods preferred by some investigators.

ELDER A. PORTER

Borrowed Children. A popular account of some evacuation problems and their remedies. By Mrs. St. Loe Strachey. Duodecimo of 149 pages. New York, The Commonwealth Fund, 1940. Cloth, \$0.75.

The first half of this book consists of informal and sketchy reports of the reception of evacuated children and is quite interesting. It is encouraging and worth reading, but do not look for advice or information about how to do it.

The latter half, more or less, is devoted to discussion with illustrations of psychic maladjustments of a kind common out of, as well as in, war. Insecurity is the main item. This part is also somewhat interesting. Of course it is a book for laymen—nicely written.

WALTER D. LUDLUM

Your Brain and Its Story. By R. J. A. Berry, M.D. Duodecimo of 165 pages, illustrated. New York, Oxford University Press, 1939. Cloth, \$2.50.

This book is the outcome of a lecture delivered by the author before a psychology association. In the words of the author he was to make clear such a complex subject as neurology by drawing on the average person's familiarity with electricity, chemistry, and business. Consequently the book has been designed and intended for the lay rather than the medical public.

It is a small, easily readable book of 158 pages with sufficient illustrations, thirty-six in number, to clarify the text. The brain is considered too much from an anatomic angle with little physiologic analysis, as the researches of Pavlov and of other modern experimental physiologists are ignored. The book may satisfy the laity.

HAROLD R. MERWARTH

The Outbreak of Polymyelitis, City of Buffalo, 1939. By Francis E. Fronczak, M.D., commissioner of health. Quarto of 48 pages, illustrated. Buffalo, New York, Department of Health, 1940. Paper.

This book consisting of 53 pages and accompanied by a separate roll of nine large graphs is concerned with a report of the investigations made by the authors during the epidemic of polymyelitis which occurred in Buffalo during the summer and autumn of 1939. The inquiry carried out followed well-established lines including a study of the geographic distribution of the cases within the city, the meteorologic conditions prevailing at the time of the epidemic, and the economic status of the families in which cases occurred as well as the conditions of sanitation and housing in which they lived. The sources of food supply and the methods of household refrigeration and of refuse disposal were not forgotten, nor was the possibility of the transmission from bathing water, household pets, or rodents.

In reading the report certain observations seem significant. A longer incubation was observed in older patients, and the disease incidence was much more prevalent in the male sex for the age group under 21 years and in the female sex for the age group over 21 years. A high proportion of cases, over 80 per cent, lived in one or two family houses. There was an apparent relation between days of high temperature and the daily increment of cases. Numerous authentic instances are recorded of the role played by the healthy carrier in the conveyance of the infection.

Several suggestions are made by the authors for the control of future epidemics and for the guidance of the National Foundation. These deductions appear entirely warranted by the observations recorded in this and other epidemics. It seems that in this report the authors have contributed to our knowledge of the epidemiology of polymyelitis.

JOSEPH C. REGAN

Report on the Sex Question. By The Swedish Population Commission. Translated and edited by Virginia C. Hamilton, M.D. Octavo of 182 pages. Baltimore, Williams & Wilkins Co., 1940. Cloth, \$2.00.

A commission on population was appointed in Sweden in 1935 to analyze various population

problems, their causes and their consequences, for the purpose of eliminating the imminent probability of continued and drastic decline in population, a matter of utmost significance, particularly in Europe

The commission reports, in a manner simple, concise, and instructive, particularly through the use of much statistical data and tables, that the decline is the result of voluntary rather than involuntary birth control. Such family limitation has been found to be caused by the change to industrial and city life and to a raised standard of living and sense of culture. The solution to the problem, therefore, is to so effect social and economic reforms as to minimize the reasons for child limitation and to inculcate the people with ideals of wholesome and happy family life. To that end the commission outlines an instructive analysis of the problem of sex with particular attention to the teaching of unarmful contraceptive methods and sex hygiene with a view to individual as well as social happiness in mind.

SAMUEL L SIEGLER

The Practice of Medicine By Jonathan C. Meakins, M D Third edition. Quarto of 1,430 pages, illustrated. St Louis, C V Mosby Co., 1940. Cloth, \$10.

The third edition of this valuable and satisfactory textbook appears two years after the second. It has been thoroughly revised and incorporates the notable advances of the interim.

The chemotherapy of pneumonia has evolved rapidly, and so we find in this volume a good account of sulfapyridine (dageenan), but the publication was too early to include mention of sulfathiazole. The author briefly presents serum therapy and advances the opinion that the "ideal treatment," particularly in severe cases, is the use of type-specific serum and chemotherapy.

MacLachlan's experience with hydroxy-ethyl-apocupreina in pneumonia is cited. This quinine derivative appears to be nontoxic and useful particularly in the presence of bacteremia, mortality 10 to 12 per cent.

Throughout the volume runs the vein of the author's physiologic approach to disease, and it is this which characterizes the work. The 562 well-chosen and well-presented illustrations call for a glazed paper, hence the weight of the book is $7\frac{1}{2}$ pounds.

Meakins' volume has quickly achieved a high point in the regard of internists and has taken its place on the shelf with Osler and Cecil.

FRANK BETHEL CROSS

Diseases Affecting the Vulva. By Elizabeth Hunt, M D. Octavo of 215 pages, illustrated. St Louis, C V Mosby Co., 1940. Cloth, \$4.00.

This is a small but comprehensive volume on vulval affections written by a dermatologist for gynecologists and general practitioners. She points out that diseases of the vulva are almost entirely cutaneous affections and that the literature up to now has been widely scattered. Vulvitis is not a synonym for dermatitis. The gynecologist will profit by reading this book. The text is simple and clear, and the plates are beautiful.

CHARLES A GORDON

Rose & Carless Manual of Surgery Sixteenth edition edited by William T Coughlin, M D. Octavo of 1,608 pages, illustrated, Baltimore, Williams & Wilkins Company, 1940. Cloth, \$9.00.

This long-famous textbook of general surgery has again been completely revised and brought up to date. The first eight chapters have been entirely rewritten and somewhat condensed. This is a welcome change since so many texts in surgery, in their initial chapters, read more like treatises on bacteriology and hematology than surgery. The author rightfully feels that the student and surgeon should refer to special texts for detailed information concerning associated subjects. Many new illustrations and several new color plates have been added, making a total of more than 250, thus greatly facilitating a real understanding of the various surgical conditions. While some subjects have been combined or condensed, much new matter has been added, especially in the matter of fractures and abdominal surgery, and one would have to consult special monographs to gain more clinical information than that found in Chapter XXVII dealing with infections of the brain and its membranes.

A final but by no means less important chapter is that dealing with the conduct and dangers of anesthesia, the various kinds of anesthetics and the methods of administration. As a ready and complete reference volume, this clear and concise text should continue in the top rank for students and practitioners alike.

ARTHUR GOETSCH

Clinical Urology By Oswald S Lowsley, M D, and Thomas J Kirwin, M D. Two volumes. Octavo of 1,684 pages, illustrated. Baltimore, Williams & Wilkins Co., 1940. Cloth, \$10.

This two-volume work of some 1,600 pages represents the latest textbook from Dr Lowsley, Dr Kirwin, and their associates at the Department of Urology (James Buchanan Brady Foundation) of the New York Hospital. The authors dedicate the book to the generous benefactors of Brady, Lawrence, and Wright, whose bequests have made possible for a considerable period of time extensive clinical and research activities, which form the basis of the valued contributions.

The book, while intended primarily for medical student, practitioner, and surgeon, should prove useful and helpful to the urologist as well. The work is well arranged and well written and is essentially one of surgical urology, including many chapters on diagnosis. Surgical operative technic is the chief feature, and the numerous illustrations have been beautifully executed by Mr William P Didusch. Photomicrographs and pathologic sections are reduced to a minimum to conserve space. Another feature is the addition of a bibliography at the end of each chapter.

The reader cannot fail to be impressed with the numerous contributions which the director, Dr Lowsley, and his staff have made to the advancement of urology as a specialty.

AUGUSTUS HARRIS

A Textbook of Pathology By W G MacCallum. Seventh edition. Octavo of 1,302

pages, illustrated. Philadelphia, W B Saunders Co, 1940 Cloth, \$10

The same high degree of excellence is maintained in this edition, four years after the last for its illustrations, photographs, and color plates, these serving to emphasize that both content and arrangement are worthy and guiding. Changes are few but completely adequate in bringing the text abreast of the present. A popular student text, its general usefulness recommends it further.

IRVING M DERBY

Obstetrics in General Practice By J P Greenhill, M D. Octavo of 448 pages, illustrated. Chicago, The Year Book Publishers, 1940 Cloth, \$3 50

This practical book on obstetric practice, with emphasis on diagnosis and treatment, is a companion volume to the author's work, *Office Gynecology*. Historical data, controversial discussions, extensive descriptions of anatomy and pathology, and conditions rarely encountered are omitted. The abundant illustrations and simple clear style of the text should make the book valuable to the physician who practices obstetrics.

The obstetric specialist will find little not already known to him, and for the student the text may not be sufficiently academic to suit his needs. General practitioners, however, should profit by it, and, if this knowledge were known to them, maternal and fetal mortality and morbidity would undoubtedly decrease.

ALEXANDER H. ROSENTHAL

The Neuroses in War By Several Authors Under the Editorship of Emanuel Miller, M A. Octavo of 250 pages. New York, Macmillan Company, 1940 Cloth, \$2 50

This excellent book is an exceedingly timely one. Without being too dogmatic it presents the opinions of several competent observers during the last World War of the effects of war on civilians and soldiers.

It should prove of inestimable value to all medical men who may be concerned with mental health in this present world crisis. The authors present the problems in a practical manner and give us a much better understanding of the treatment of such states as "shell shock," "effort syndrome," etc.

While the book is the result of collaboration of several authors, there is a cohesion and continuity to it which speaks well for its editor.

JOSEPH L ABRAMSON

The Theory and Practice of Anaesthesia. By M D Nosworthy, M D. Duodecimo of 223 pages, illustrated. New York, Chemical Publishing Company, 1940 Cloth, \$4 25

This book appears to be intended for the use of those who are learning anaesthesia. The author emphasizes the importance of learning the principles of anaesthesia with the simpler, old-time fundamentals for study. Here he conforms to the older British custom which some anaesthetists in Great Britain seem to be discarding. Improvement in anaesthesia has produced a multiplication of methods which bewilder the

beginner and sometimes the experienced, and to add to this perplexity there is also a divergence of opinion about which is best. The author helps the student to sift out the advantages and indications for each method or agent, and he bases his opinion on his own personal experience. The discussion of the physiology of anaesthesia covers the latest theories of a much debated question, and shock is given a chapter for its anesthetic connotation.

Anesthesia practice in Great Britain apparently follows the same general lines as in this country. Along with the usual inhalation anesthetics, the barbiturate group and spinal anesthesia all seem to have their usual places.

G W TONC

Multiple Human Births Twins, Triplets, Quadruplets, and Quintuplets. By Horatio H Newman, Ph D. Octavo of 214 pages, illustrated. New York, Doubleday, Doran & Company, 1940 Cloth, \$2 50

The author, a professor of zoology, has written this most interesting book on multiple human births in language scientifically correct and yet within the understanding of the layman. There are many books on this subject, but this is the only one written for the general reader which covers the whole field so that it is adequate for reference.

The volume is fascinating reading for those who are interested in twins, be the interest intimate or remote. Here can be found the answer to all questions in regard to the subject. While the language of the book is simple, the scientific facts are correct. Even if the only interest the reader has in multiple births is the Dionne quintuplets, still we are sure that the book will not be laid away until it has been completely read.

WM SIDNEY SMITH

Pathogenic Microorganisms. A Practical Manual for Students, Physicians and Health Officers By William H Park, M D, and Anna W Williams, M D. Eleventh edition. Octavo of 1,056 pages, illustrated. Philadelphia, Lea & Febiger, 1939 Cloth, \$8 00

Since its very inception in 1899, this work has been an authoritative publication and in the keeping of eminent workers. The present volume may well be termed a memorial edition, since it is the last to appear with Dr Park as collaborator and stresses his meritorious activities. The general and practical amplitude of each edition is too well known to all workers in bacteriology and allied sciences for elaboration of the present one. Bringing up to date every available item in a rapidly enlarging subject, particular sections are new or almost entirely rewritten. Notable are the subjects of bacterial variation, yeasts and molds, protozoa, and filtrable viruses. The bibliography is still further enlarged by the communications of these last years. Recommendation is ostentatious for such a standard work.

IRVING M DERBY

Controlled Fertility An Evaluation of Clinic Service. By Regine K. Stux, M D, and Frank W Notestein, Ph D. Octavo of 201 pages, illustrated. Baltimore, Williams & Wilkins Co, 1940 Cloth, \$3 00

5 DISTINCT VI-SYNERAL PRODUCTS FOR 5 DIFFERENT AGE GROUPS . . .

INFANTS and
CHILDREN

ADOLESCENTS

ADULTS

EXPECTANT
and NURSING
MOTHERS

SPECIAL GROUP
(Middle-Aged and
Aged)

VITAMINS ALONE ARE NOT ENOUGH!
BECAUSE VITAMINS ARE BETTER UTILIZED WITH
VI-SYNE AL SUPPLIE T ' ALS

[Continued from page 519]

It is the purpose of the authors to offer statistical data derived from actual study of various groups of individuals (vocational, educational, religious), rather than by the erroneous method of anonymous questionnaire, to evaluate the services of a birth control clinic.

Such a clinic is effective not only in teaching methods of contraception but also in obtaining success in such practices and as an agency for public health and welfare.

The Birth Control Clinical Research Bureau in New York City is definitely shown to have achieved its purpose. It has been influential toward the betterment of maternal and infant health and happiness through adequate and intelligent family planning.

The statistical tables and charts used are detailed and instructive, but many of them, although easily comprehensible to the statistician, are too involved for general reading. The volume is an excellent treatise on the aims and accomplishments of birth control groups.

SAMUEL L. SIEGLER

Management of the Cardiac Patient. By William G. Leaman, Jr., M.D. Octavo of 705 pages, illustrated. Philadelphia, J. B. Lippincott Co., 1940. Cloth, \$6.50.

This volume is an excellent treatise on the management of the cardiac patient. The reviewer appraised it by looking up problem after problem that might be met in office and hospital practice and found each subject handled in a sound, practical, and conservative manner. The arrangement of the material is good, and it is especially pleasing to note that the etiologic classification has been followed. It is difficult to pick out chapters of special merit. That on syphilitic cardiovascular disease is excellent. The author has produced a work that is fundamentally sound and should be of practical value to practitioners of medicine.

E. P. MAYNARD

Diseases of the Digestive System. A Textbook for Students and Practitioners. By Eugene Rosenthal, M.D. Octavo of 394 pages, illustrated. St. Louis, C. V. Mosby Co., 1940. Cloth, \$8.50.

With 234 illustrations on 384 pages, this book is probably the most profusely illustrated treatise yet published on diseases of the digestive system. While this feature seems to add clarity to the text, it does appear to make the treatment of the material too simple and elemental. Without entering into a discussion over the merits of the material itself, one notes that the medicaments mentioned are much too frequently European rather than American in origin. On the whole the book is interesting but fails to fulfill its purpose of providing an adequate textbook in the field of gastroenterology for him who needs it most—the nonspecialist in the diseases of the digestive system.

BENJAMIN M. BERNSTEIN

Foreign Bodies Left in the Abdomen. The Surgical Problems, Cases, Treatment, Prevention. The Legal Problems, Cases, Decisions, Responsibilities. By Harry S. Crossen, M.D., and David F. Crossen, LL.B. Quarto of 762

pages, illustrated. St. Louis, C. V. Mosby Co., 1940. Cloth, \$10.

All surgeons and operating-room nurses should familiarize themselves with this book before starting their careers. However, at this early stage they will probably feel that the grave dangers enumerated and the painstaking methods devised to prevent such accidents are exaggerated. It would, therefore, be well for them after a short period of active work to go over the book again. Hospitals might find it an economy to keep copies handy in their operating suites and libraries.

The volume is the work of two authors, one presenting the medical and the other the legal point of view of this tragic subject. It is important that the surgeon should understand his exact legal, as well as moral, responsibilities.

The reviewer believes there is one small defect in that the title specifies the abdomen, whereas, the book itself goes further and covers the rest of the body. The complications following a foreign body left in the abdomen are probably more often fatal to the patient than those left under the flaps of a mastectomy closure, in a hernial repair, or even within the pleura, but the legal consequences to those responsible are almost the same.

We feel the most important function of this carefully prepared book is to call to the attention of the experienced, as well as the tyro, the ease with which foreign bodies may be left in the patient and the tremendous discipline necessary to even approach perfection in preventing this all too common accident. The frequency of this tragedy needs all the emphasis here given by the listing of hundreds of reported cases, particularly when it is considered that a far greater percentage probably never appears in the literature.

WM. H. FIELD

The Chemical Composition of Foods. By R. A. McCance and E. M. Widdowson. Octavo of 150 pages. New York, Chemical Publishing Company, 1940. Cloth, \$2.50.

Research studies in human nutrition demand that there be exact knowledge as to the chemical composition of foods, not only qualitative but quantitative. McCance and Widdowson have arduously produced such data and earned through a rather thankless job, save to the investigator who must immediately know the magnesium content of artichokes or the sodium content of boiled new potatoes as compared with old potatoes.

From the American point of view the most valuable portion of the handbook is that which gives the complete quantitative composition of 100-Gm. portions of an endless variety of foods both raw and cooked. The statistical data in ounce-quantities of foods are of less usefulness because of the fact that a conversion factor of 28.4 Gm to the ounce has been used rather than the conventional 30 Gm per ounce. Similarly, the values of recipes of the English dietary would in general be different from those of dishes used in this country. However, for straight fact on food analysis this book is unsurpassed.
